

Developments in convective scale assimilation at the UK Met Office

Bruce Macpherson, Gareth Dow, Bob Tubbs,

Peter Francis, Gordon Inverarity, Richard Marriott

Contents

This presentation covers the following areas

- Description of UK 1.5km DA system
- Recent upgrades
- Assimilation & Observation impacts
- Future plans

UK 1.5km DA cycling

- ❑ **8 three-hour assimilation cycles per day**
- ❑ **Forecasts to t+36 every 3 hours**
 - **Observation cut-off hh+ 75min**
 - **Lateral boundaries from hh-3hr run of 25km Global model at DT 03, 09, 15, 21 UTC**
 - **Lateral boundaries from hh-6hr run of 25km Global model at DT 00, 06, 12, 18 UTC**

UK 1.5km DA

- ❑ **3DVAR (with FGAT) + IAU for all observations**

***except* Latent Heat Nudging for radar-derived surface rain rate**

- ❑ **VAR grid is uniform 3km resolution over whole domain (including area of variable UM resolution)**
 - **Variable → fixed grid interpolation for VAR linearisation states and ‘model observation’ columns**
 - **Fixed → variable grid interpolation for VAR increments**
- ❑ **Adaptive vertical grid**

UK 1.5km – extra observations *not* assimilated in global model

- ❑ radar-derived surface rain rate (hourly, 5km resolution)
- ❑ visibility from SYNOPs (hourly)
- ❑ T_{2m} & RH_{2m} from Highways Agency roadside sensors (hourly)
- ❑ Doppler radial winds (3-hourly)
- ❑ SEVIRI Channel 5 radiances above low cloud
- ❑ GeoCLOUD cloud fraction profiles (3-hourly, 5km resolution)
 - zero cloud down to cloud top, missing data below
- ❑ cloud fraction profiles from SYNOPs (3-hourly)
 - zero cloud up to cloud base, missing data above

UK 1.5km – forecast error covariances

❑ Lagged NMC method + CVT software

- 152 UK1.5 forecast pairs
- $t+6 - t+3$
- Jan – Jun 2012

❑ Horizontal scales

(leading vertical mode)

- | | |
|---------|-------|
| • psi | 150km |
| • chi | 190km |
| • Ap | 70km |
| • mu | 30km |
| • log m | 60km |

} *smaller*

- ## ❑ Now derived from training data & consistent with variances (previously, fixed values specified for all modes)

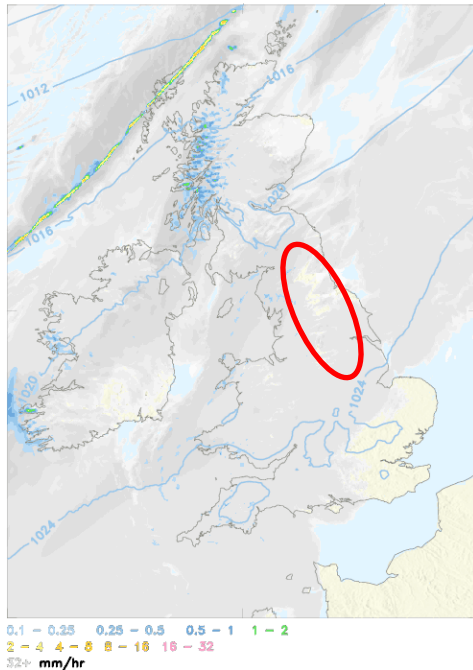

Recent Upgrades (since July 2011)

- ☐ new humidity control variable
- ☐ new 'CVT' covariances (shorter horizontal scales)
- ☐ additional satellite data
 - ☐ SEVIRI Ch 5 above low cloud
 - ☐ high-resolution AMSU-B
- ☐ replacement of MOPS cloud data with direct assimilation of GeoCLOUD (satellite) and SYNOP cloud fraction obs
- ☐ increasing Doppler radial wind coverage across UK

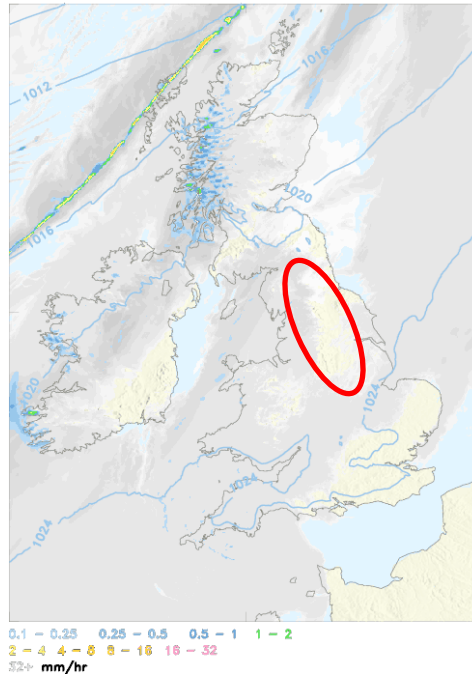

Impact of CVT covariances on Sc (15th March 2012, T+7)

Impact of SEVIRI Ch 5 + AMSU-B on upper-tropospheric humidity

(13 Feb 2012 case 03Z)

- SEVIRI data improves humidity in the upper troposphere
- AMSU-B data improves humidity above the cloud top
- Complement each other

UK Index Impacts in UK 1.5km (~3 weeks winter 2011, t+0→t+24)

- | | |
|--|--------------|
| A. No UK analysis - latest Global lateral boundary forcing only | 0 % |
| B. as A + continuous UK assimilation with 'standard obs' | +6.5% |
| C. As B + extra obs not in global system | +7.3% |

*(cf ~2% annual increase in UK Index &
~10% added value over global NWP system)*

UK Index Impacts in UK 1.5km (~4 weeks winter 2011, $t+0 \rightarrow t+24$)

- | | |
|---|-------|
| A. Downscaler –from
interpolated Global
analysis with fixed
aerosol | 0 % |
| B. as A + full continuous
UK assimilation with
prognostic aerosol | +5.1% |

UK Index Impacts in UK4

Observation denial experiments (~5 weeks winter, $t+0 \rightarrow t+24$)

Surface	+2.9%
Satellite	+1.7%
Upper Air	+2.1%
(excluding aircraft)	
Aircraft	+2.0%
Radar	+2.0%
“Extra”	+0.5%

(all obs networks not in
global model)

Gareth Dow

Extra Benefit of UK DA system compared to downscaled global analysis

- Most consistent benefit from assimilating 'conventional' observations at **higher** (4km, 1.5km) **resolutions**
- Mixed performance from the **extra observation types** which, on occasion, can reduce the benefit of the full UK DA system (mainly an issue with MOPS cloud in Sc situations - have recently moved from MOPS cloud analysis to GeoCloud + Surface Cloud in UK1.5)

Gareth Dow

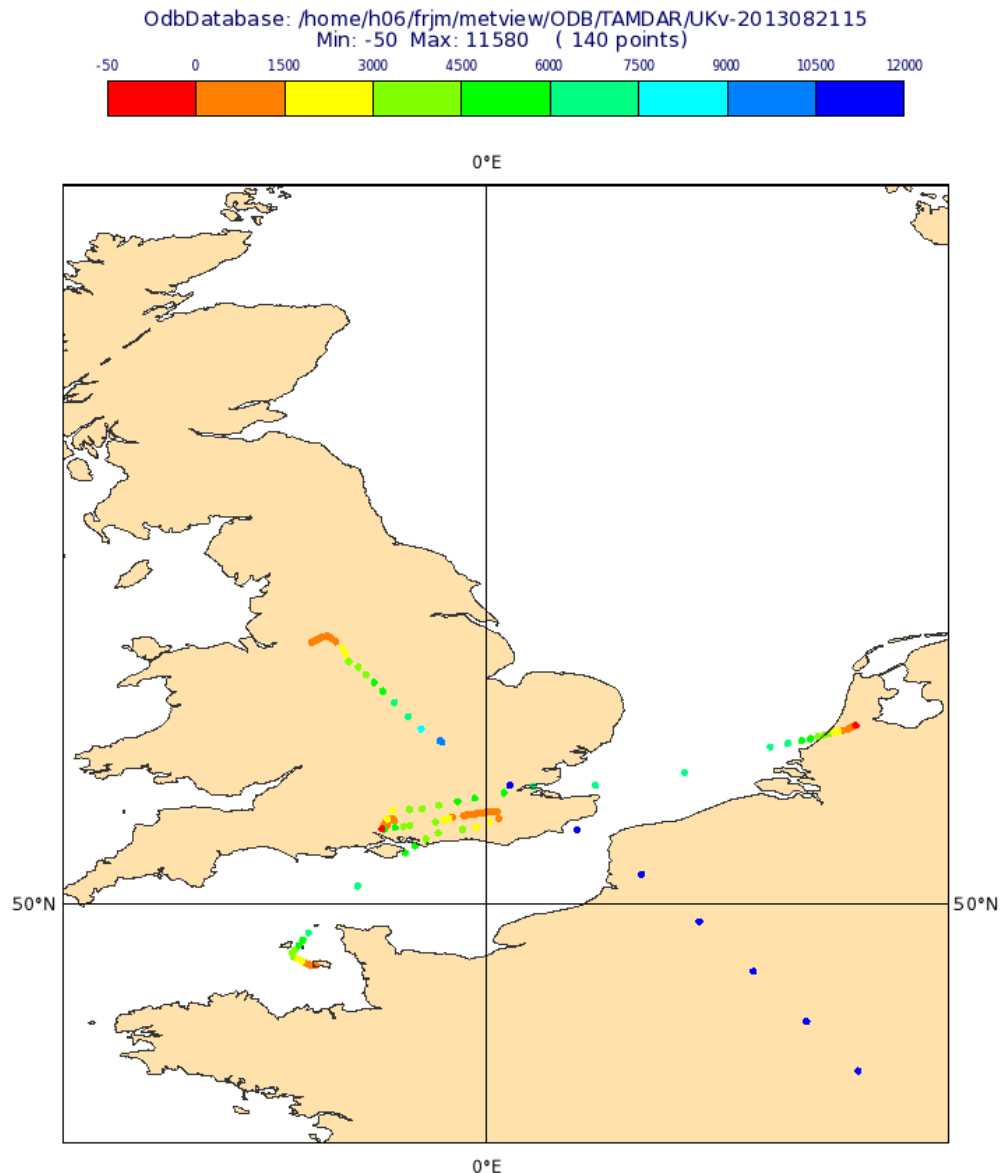

UK 1.5km DA – future developments in *observations*

- ❑ BUFR sonde data (with balloon drift)
- ❑ high resolution AMV data
- ❑ more roadside sensor data (England → whole UK)
- ❑ improve cloud assimilation
 - increase weight for satellite & surface reports
 - avoid assimilating cloud tops close to existing cloud in model background
 - derive cloud top height observations within each assimilation cycle, using latest model background vertical profiles (instead of within external AUTOSAT system)

Monitoring of Flybe TAMDAR data

- since 20th Aug 2013
 - 3 aircraft so far
(~200 obs per day each)
 - wind quality ~ AMDAR
 - T slightly worse
 - RH similar quality to US
TAMDAR
- [~15-20% sd for (o-b) below
500hPa]

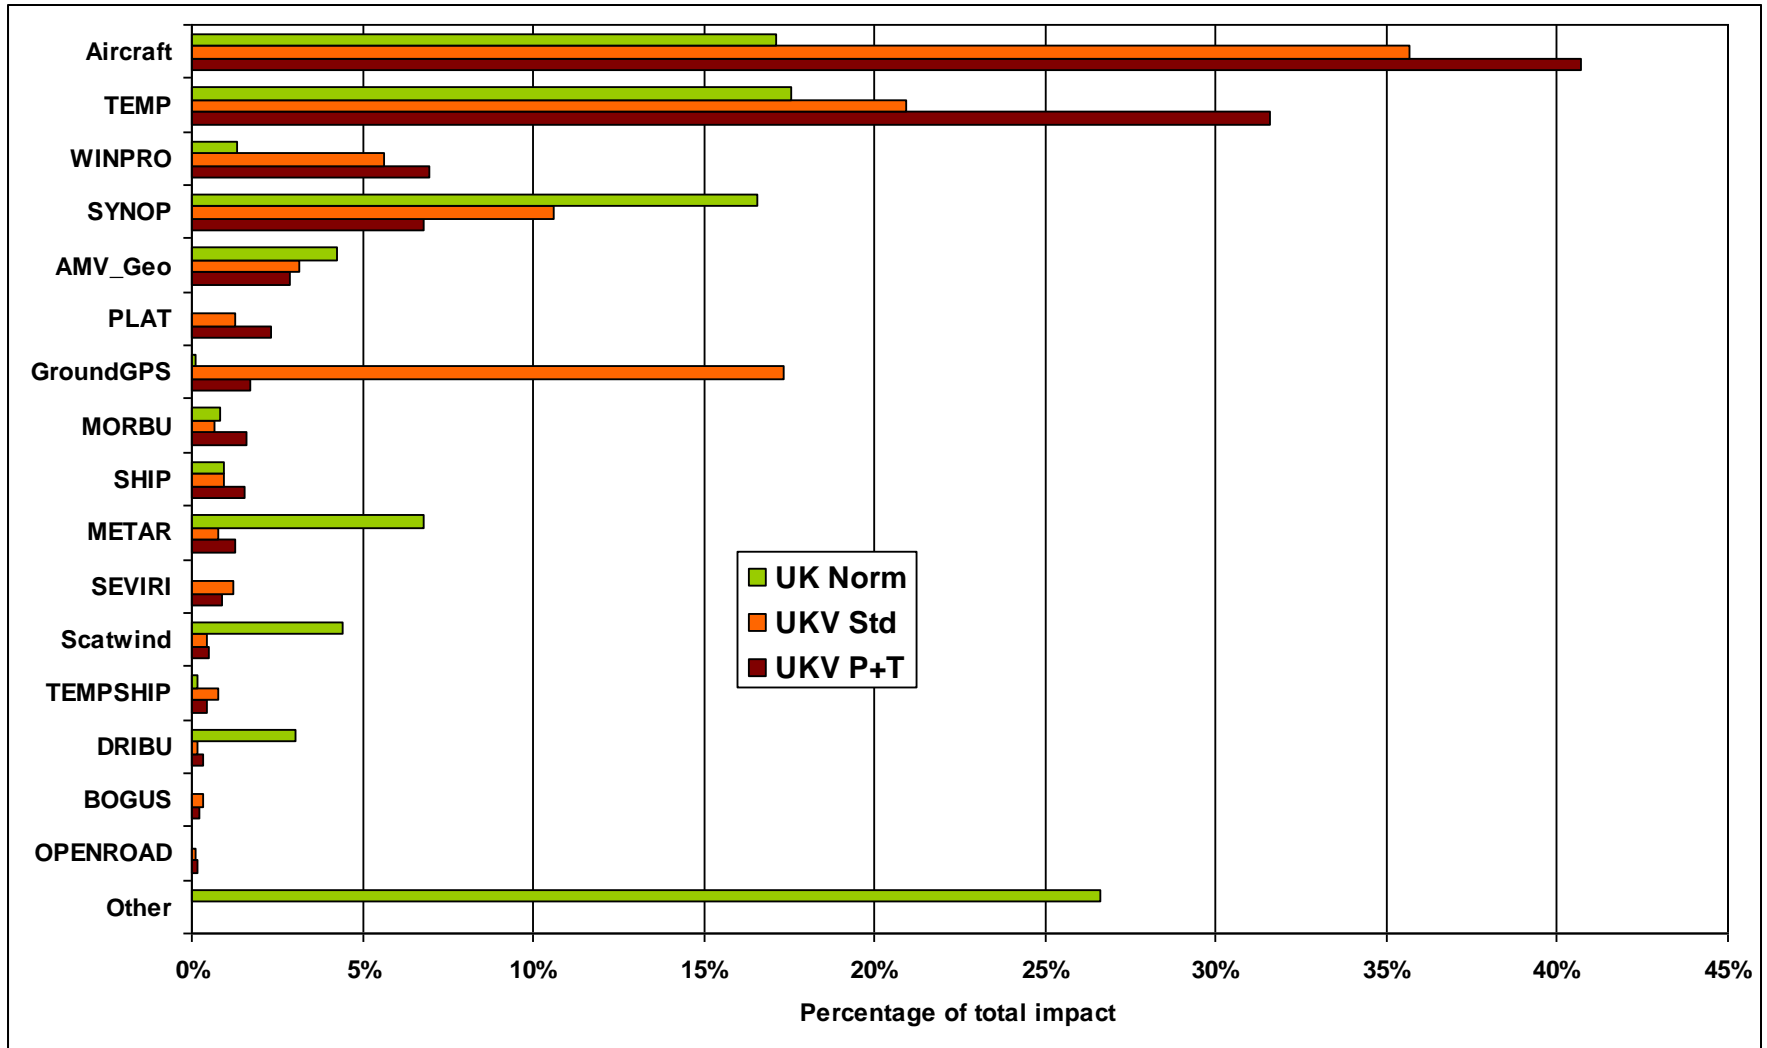

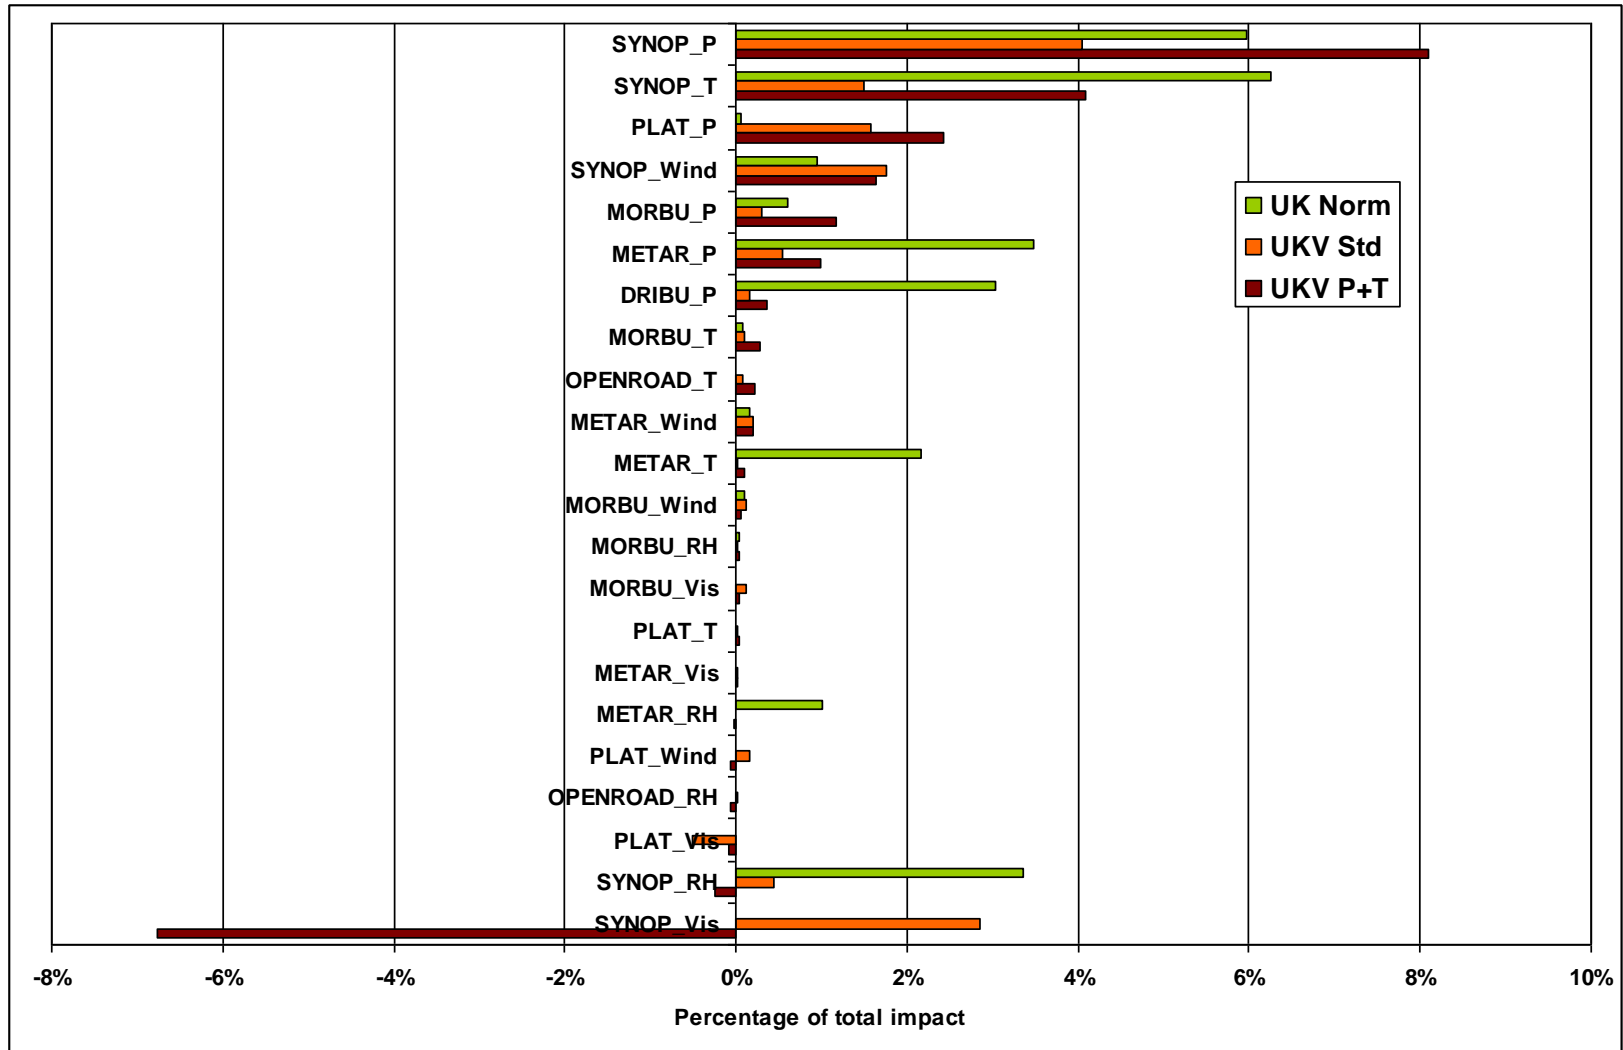

FSO tool at convective-scale

- ☐ challenge of model non-linearities
- ☐ linear Perturbation Forecast model and adjoint valid only for short forecast periods (3-6 hours)
- ☐ verifying analyses used within forecast error norm are assumed to be independent of the forecasts – not good assumption at $t+3$
- ☐ preliminary work with P/T norm at $t+3$, maybe including v and q up to $t+6$?
- ☐ initial comparison with global FSO results for UK area with 'standard' moist energy norm

All ob-types – Total impacts

Surface types – Total impacts

FSO – Summary

- ❑ Linearisation tests.
 - case 1 – T, P pass at T+3; Only P passes at T+6.
 - case 2 – U, V, W, T, P, q pass at T+3; T, P, q pass at T+6.
- ❑ Boundary conditions seem to account for about half of the T+3 forecast impact.
- ❑ TEMP, Aircraft and WINPRO show large impacts in the UKV results.
- ❑ GNSS gives a large impact on the standard UKV error norm – presumably on the humidity component.
- ❑ Fractions of beneficial obs seem to be larger in the UKV results. (This could reveal a bias in the verification.)
- ❑ Next step is to implement an obs-based forecast error metric.

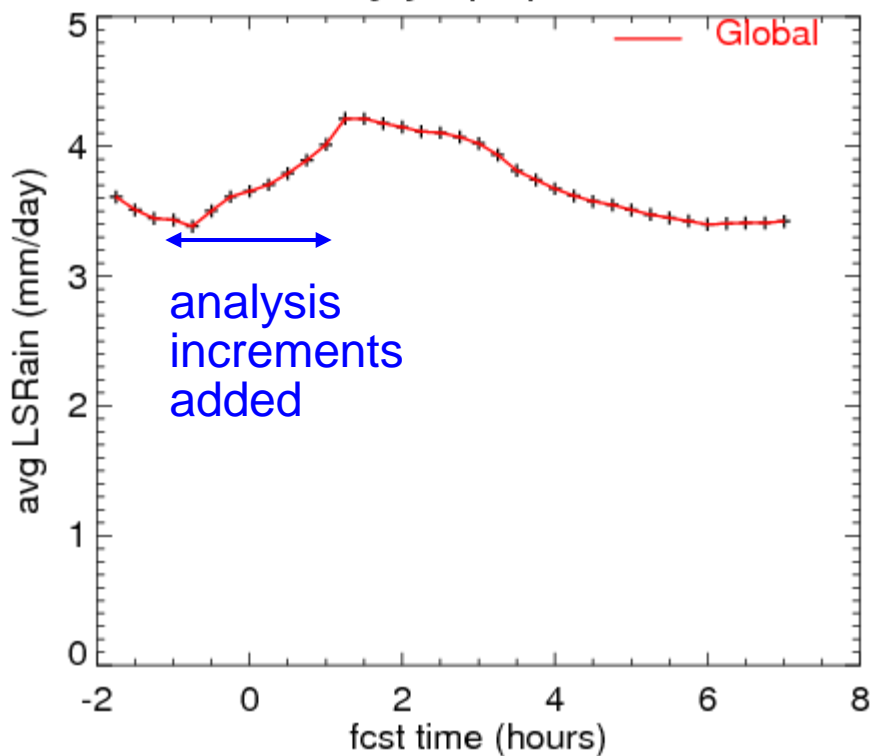

UK 1.5km DA – future developments in *observations* - II

- ☐ high resolution IASI data
- ☐ CrIS advanced IR sounder
- ☐ radar reflectivity
- ☐ radar refractivity

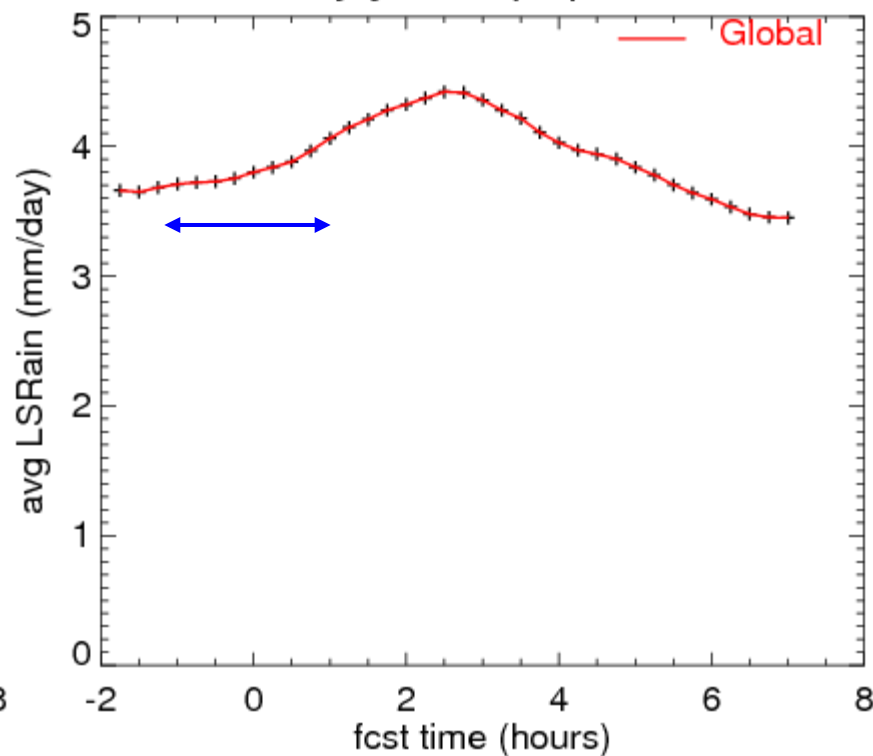

Bypass moisture incrementing operator (ie add q_t' to q)

– impact on spin-up

Control

Control+bypass

UK 1.5km DA – future developments in *algorithms*

- ❑ **test ‘affordable’ 4DVAR on UK-wide configuration**
 - **build on Nowcasting Demonstration Project (NDP) experience**
 - **apply on 3rd (final) step of adaptive vertical grid sequence**
- ❑ **2016-17 - Operational implementation of next-generation NWP-nowcasting system**

Questions?

Additional slides

New Humidity Transform

- $\mu = (q_T' - hcT') a / q_{\text{sat}}(\mathbf{b})$
- q_T' increment of total q – including cloud
- T' temperature increment
- $h = h(\text{RH}\mathbf{b})$ gives “balanced” q_T increment from T'
- $a = a(\text{RH}\mathbf{a}, \text{RH}\mathbf{b})$ is normalising factor so that $\sigma(\mu) \approx 1$ this reduces under/overshoots
 - h and a are derived from training data
- If $a = a(\text{RH}\mathbf{b})$ then we have linear transform

Met Office

Adaptive Mesh Transform

(Piccolo & Cullen, 2011: Q. J. R. Met. Soc., 137, 631-640)

(Piccolo & Cullen, 2012: Q. J. R. Met. Soc., 138, 1560-1570)

- ❑ aims to change the vertical background-error correlations by moving the vertical levels to concentrate mesh points around temperature inversions.
- ❑ movement of the levels is guided by a scalar ***monitor function***, chosen to be a function of the *static stability* which strongly controls vertical mixing in the atmosphere and thus probably the vertical correlation structure of model variables.
- ❑ in the Met Office VAR system, the adaptive method is implemented as an extra transformation in the sequence of variable transformations used to simplify the background term of the cost function:

$$\delta \mathbf{x} = \mathbf{U} \boldsymbol{\chi} = \mathbf{U}_p \mathbf{U}_a \mathbf{U}_v \mathbf{U}_h \boldsymbol{\chi} \quad \text{and} \quad \mathbf{B} = \mathbf{U} \mathbf{U}^T$$

where \mathbf{U}_a is the "adaptive mesh transform", placed between the parameter transform \mathbf{U}_p and the vertical transform \mathbf{U}_v

Adaptive Grid Formulation

The first step of the \mathbf{U}_a transform is to calculate a *monitor function* $M (>0)$ in physical space $z \in [0,1]$:

$$\int_0^1 M(z') dz' = 1$$

The second step is to generate the adaptive mesh in physical space by defining a computational coordinate $\zeta \in [0,1]$:

$$\zeta(z) = \int_0^z M(z') dz'$$

The map from computational domain to physical domain is thus defined by a unique one-dimensional map which connects intervals of a prescribed length.

Finally, the control variables χ which will be generated at points ζ by the vertical transform are then interpolated to the true levels z .

Choice of the Monitor Function

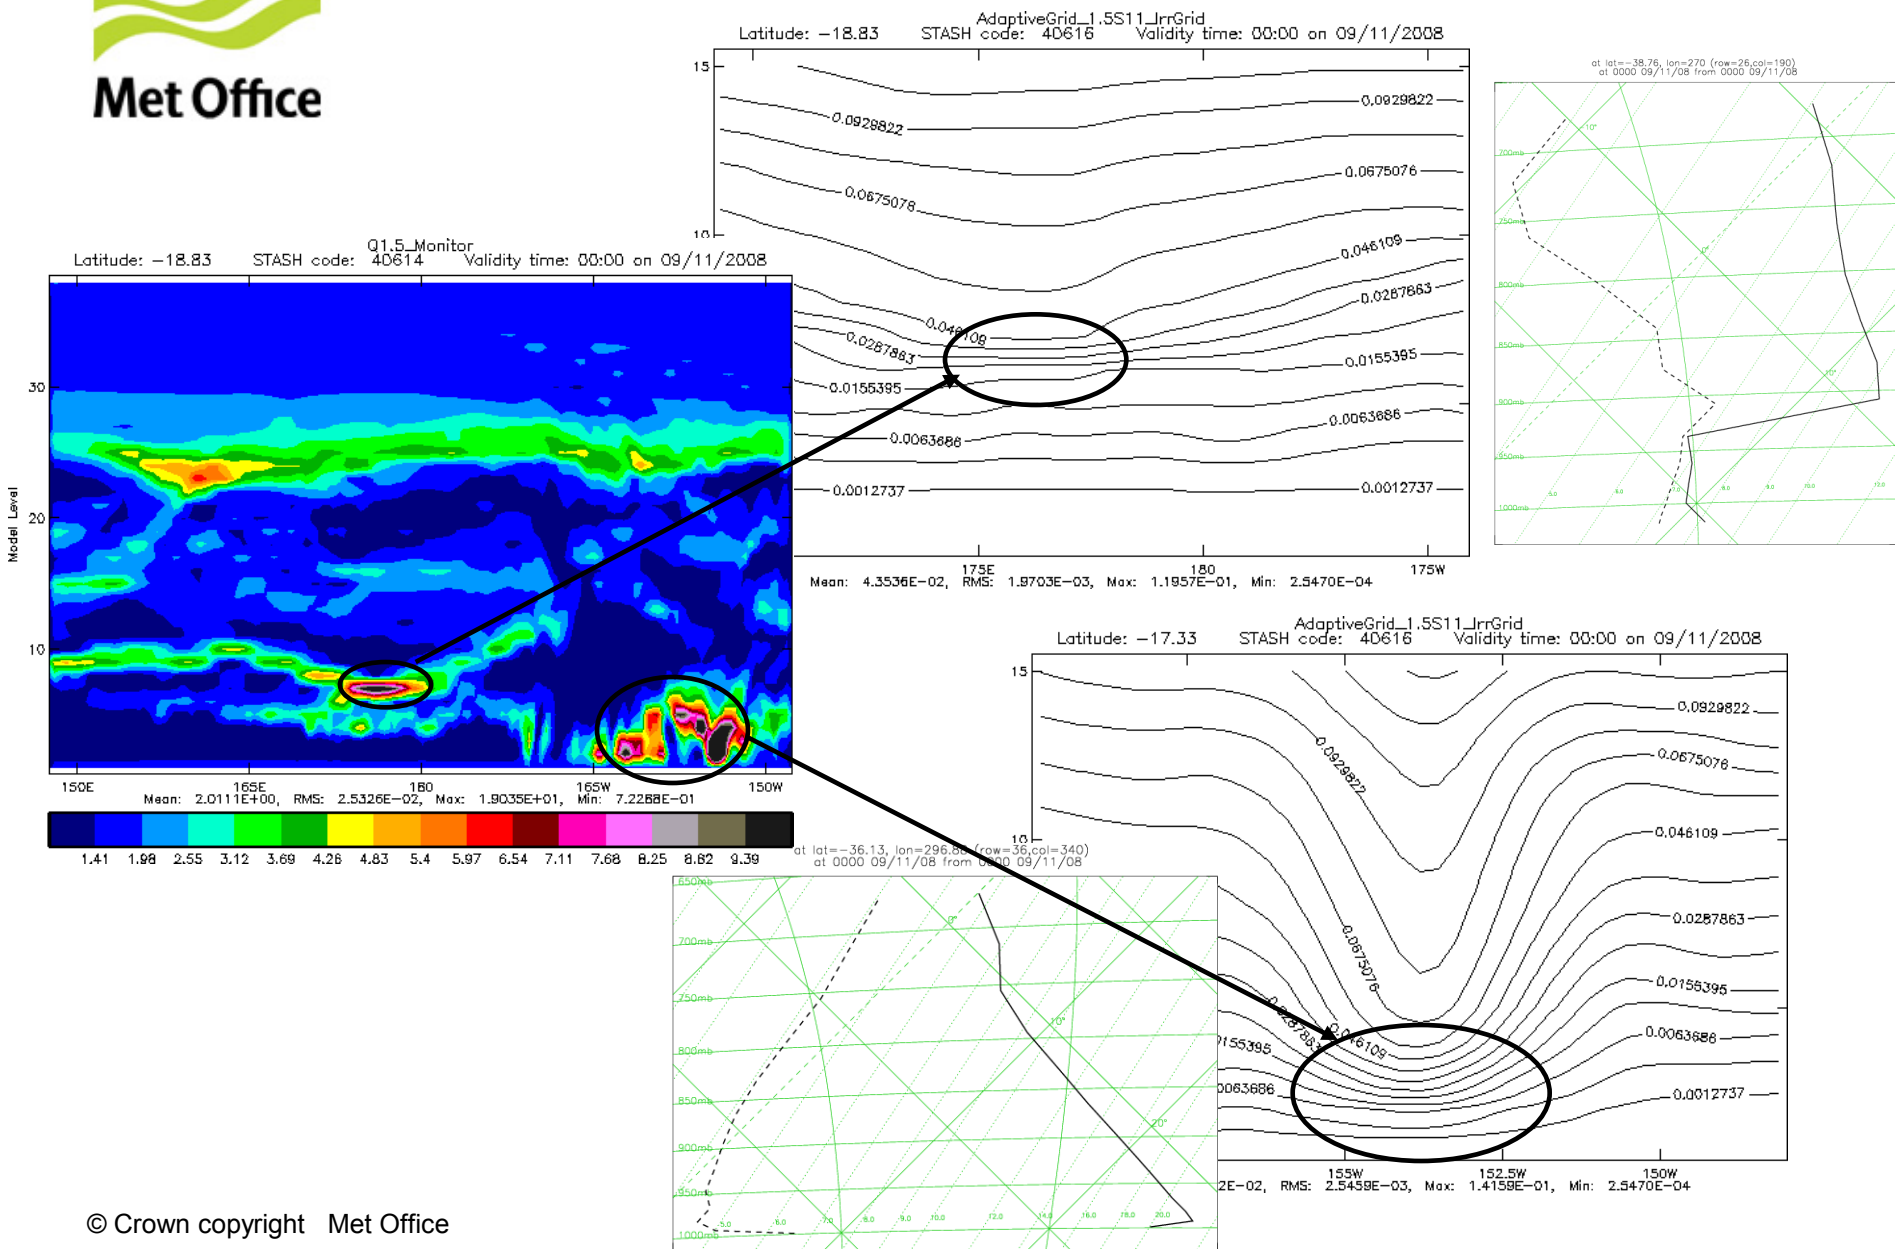

$$M = \sqrt{1 + c^2 (\partial\theta/\partial z)^2}$$

$M > 0$ and can be modulated by a scaling factor c .

If $c = 0$, the computational grid and the physical grid are the same.

Since mesh points will be clustered where the monitor function is large, this choice of M will cluster mesh points in regions of large static stability.

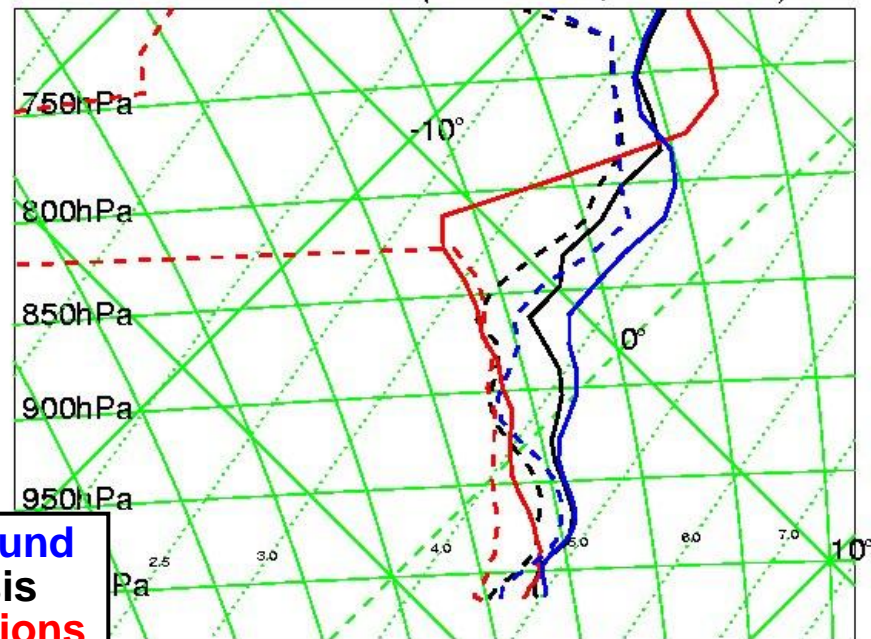

Monitor Function and Adaptive Grid

3 Jan 2011 00z: Camborne

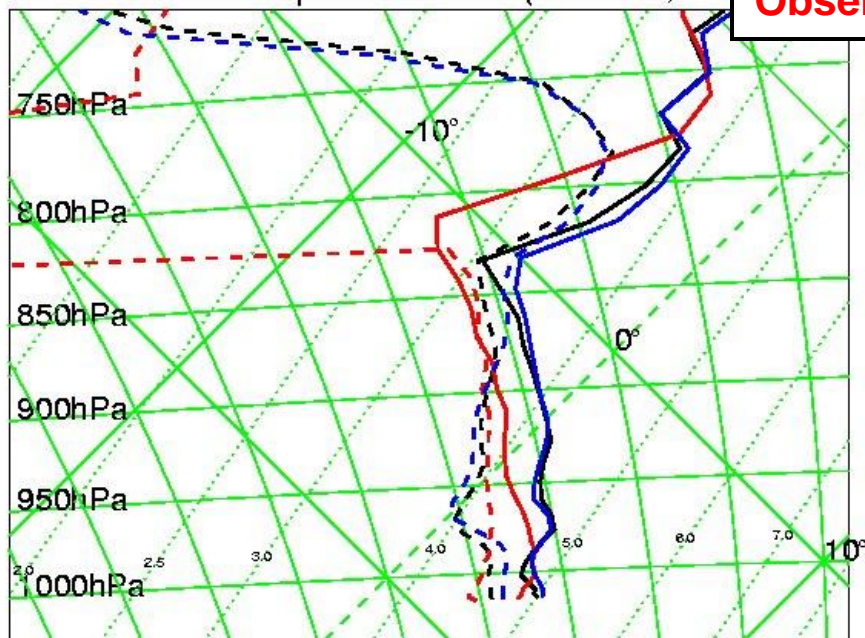

The monitor function is based on the background state: if the inversion is not present, the vertical grid does not change.

Control Camborne (lat=50.22,lon=-5.33)

**Background
Analysis
Observations**

AG Theta 0.75 LSplus Camborne (lat=50.22,lon=-5.33)

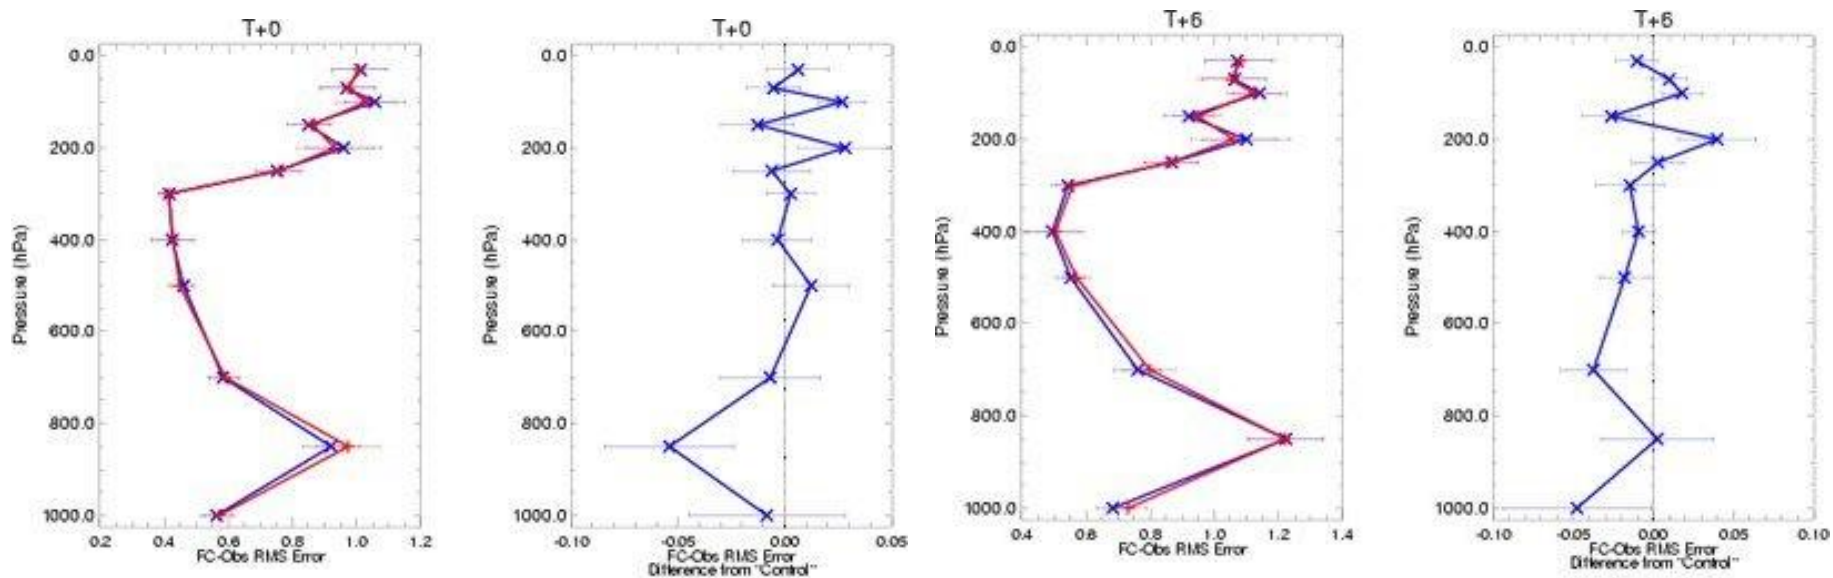

When the monitor function is based on an updated background-state using the observation's information in the minimisation process, the analysis has a clearer inversion.

Met Office

Impact of adaptive grid - analysis vs sonde observations

Temperature RMS error over the winter period

Results from the full coupled analysis/forecast system:

- small improvement of temperature RMS error versus sonde profiles in the lower atmosphere for both winter and summer cases up to T+ 6h
- (also slight improvement for cloud base height and T2m)

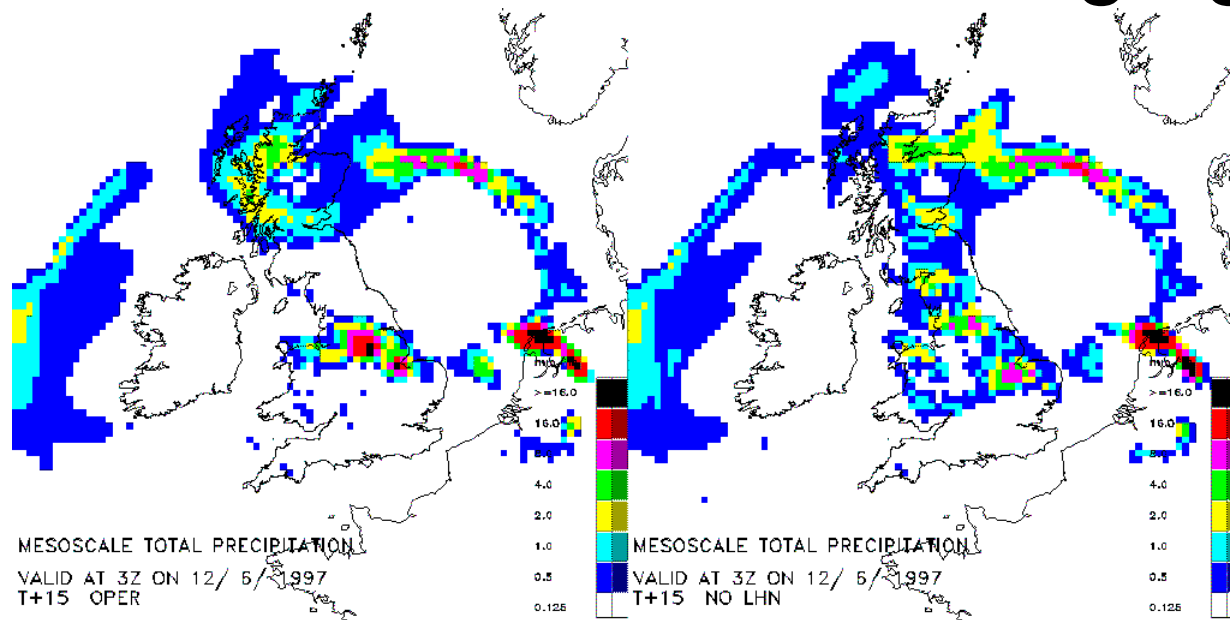

Latent Heat Nudging radar rain rate assimilation

(Jones and Macpherson, 1997: Met Apps, 4, 269-277)

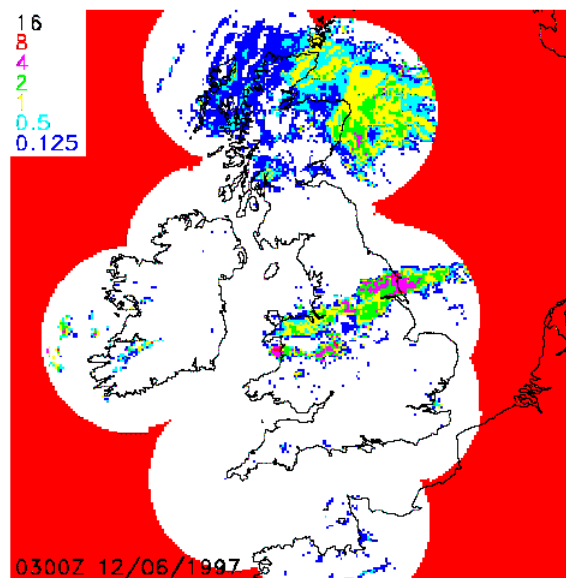

- hourly radar rain rate composites at 5km resolution
- pre-processing includes clutter and anaprop removal, bright band and vertical profile of reflectivity corrections, gauge calibration
- weight during assimilation depends on radar range and beam height above freezing level

MOPS Cloud assimilation in VAR

(Renshaw & Francis, 2011: Q. J. R. Met. Soc. **137**: 1963–1974)

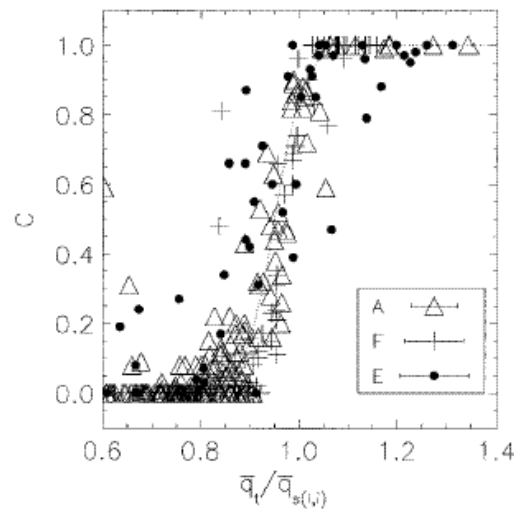

- Operational in NAE & UK models from November 2008, replacing earlier nudging scheme
- Uses 3-d gridded cloud fractions from nowcasting scheme
- Input data are satellite cloud top height and cloud mask + surface reports of total cloud cover and layer cloud amounts

Control Variable

- extra cloud control variable difficult
- have to use single moisture variable
- for now we use RH and diagnose cloud fraction = $f(\text{RH})$

Visibility forecasting and assimilation

- **UM aerosol**

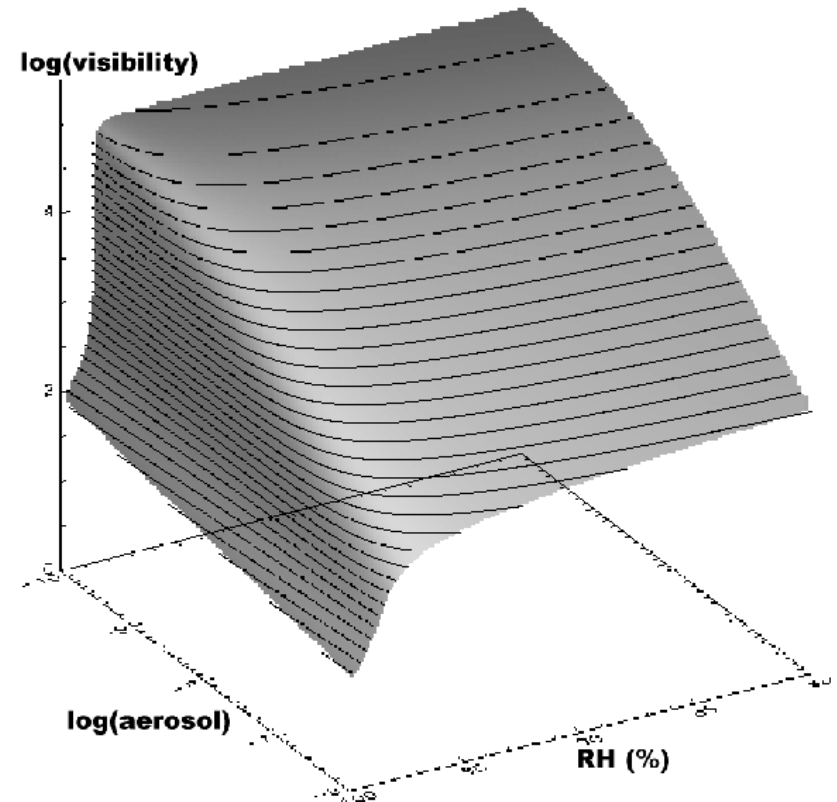

- single aerosol mass mixing ratio m
- tracer advection
- boundary layer mixing
- emission sources
- removal by precipitation

- **visibility diagnosis**

- humidity
- aerosol
- temperature
- precipitation rate

- **4D-Var**

- PF advection of $\log(m)$

UK1.5km Domain

Variable
zone

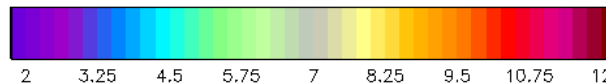

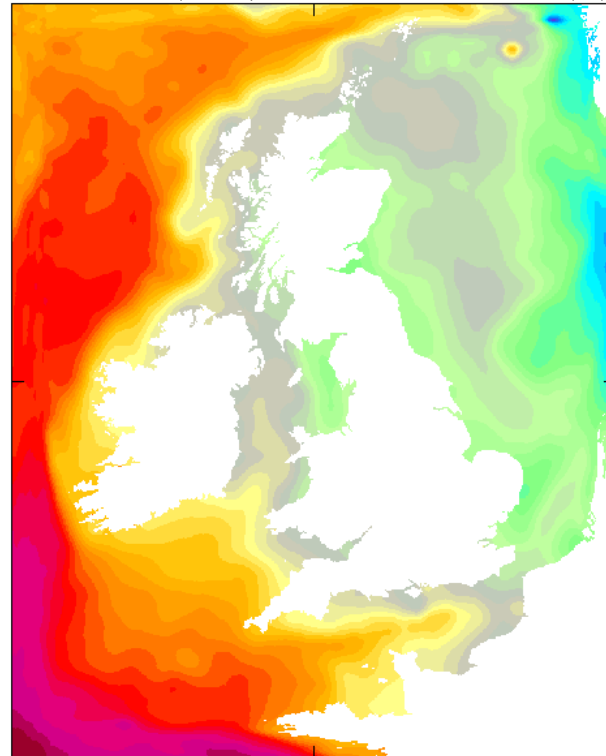

744(622) x 928(810) points

UK 1.5km – SST

☐ updated daily from OSTIA system (~6km resolution)

SST ANALYSIS: UKV (1.5km) MODEL. Date of field is 25/3/2010

UK 1.5km – soil moisture analyses

- ☐ updated daily from interpolated global model analysis (EKF with increments from screen level temperature and humidity observations plus ASCAT soil wetness observations)
- ☐ global values used over whole model domain
- ☐ interpolation conserves beta (moisture availability)
- ☐ (long term) introduce dedicated land surface assimilation for UK model via EKF
