

**Effect of assimilation of radar
reflectivity and satellite data on a very-
short range forecast of heavy
convective rainfalls**

Content

- NWP model
- Assimilation methods
 - Radar reflectivity
 - Satellite
- Examples
- Conclusions

NWP model COSMO 4.0

- Non-hydrostatic
- $\Delta x = 2.8 \text{ km}$, $\Delta t = 30 \text{ s}$
- explicit precipitation
- hydrometeors
 - rain
 - snow
 - ice
 - graupels

- $\Delta x = 10 \text{ km}$
- cumulus parameterization

Assimilated data

- Radar reflectivity
 - Two C-band radars
 - Resolution 1km x 1km, $\Delta t=10$ min., CAPPI 2km
 - Z-R $\alpha=200, \beta=1.6$
 - Radar + gauge
- Satellite data - MSG
 - The same projection as radar data
 - $\Delta t=15$ min., resolution about 4km x 4km
 - Channels: IR10.8 μm , VW6.2 μm

Assimilation of radar data

WVC (water vapour correction):

Correction of q_v is based on the difference

$D = \text{“observed precipitation”} - \text{“model precipitation”}$

method: nudging

IF($D > 0$)

$$q_{v,k}^{\text{new}} = q_{v,k} + \text{DIF}$$

k ... vertical level

ELSE

$$q_{v,k}^{\text{new}} = q_{v,k} - \text{DIF}$$

DIF depends on:

- D at ground
- z (artificial vertical profile)
- empirical constants

Assimilation of MSG data

$$q_{v,k}^{\text{new}} = q_{v,k} + \text{DIF}$$

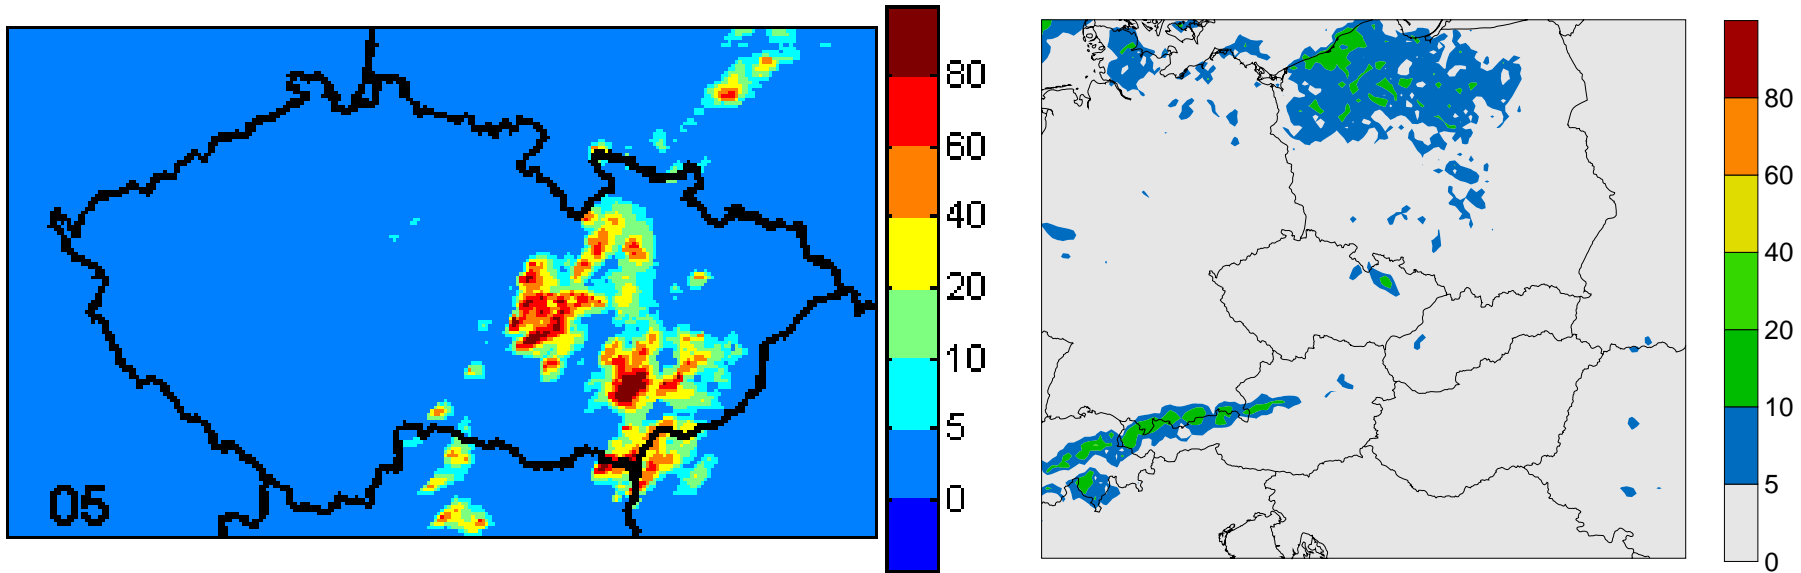

DIF > 0

- Precipitating clouds ... $\text{IR10.8} - \text{VW6.2} \leq 8 \text{ K}$
- $q_r + q_s + q_g = 0$
- $z < 10 \text{ km}$ (cloud top derived from IR10.8)

DIF depends on:

- Difference of $\text{IR10.8} - \text{VW6.2}$
- z

Conclusions

- Assimilation significantly improves precipitation forecast for the next 3-5 hours.
- In general the assimilation of combined radar and MSG data yields better or comparable forecasts than the assimilation of radar data only.
- Problems with MSG data:
 - Relationship: MSG data – rain rates
 - The assimilation of combined radar and MSG data sometimes overestimates precipitation forecasts.
- The assimilation influence precipitation forecast for the next 3-6 hours.
