

**Met Office**

# Doppler Radar Assimilation Trials

*Helen Buttery – David Simonin – Sue Ballard*

# Introduction

- Doppler radial winds:
  - Reflected radar beam has a frequency shift due to the velocity along the beam direction of the raindrop (the Doppler effect).
  - Have a measurement of radial velocity anywhere along the radar beam where there is rain.
  - But no information about the tangential velocity.

Met Office

# Introduction

6 radar stations currently providing Doppler radial wind measurements (plans to upgrade whole network)

4 used in these trials

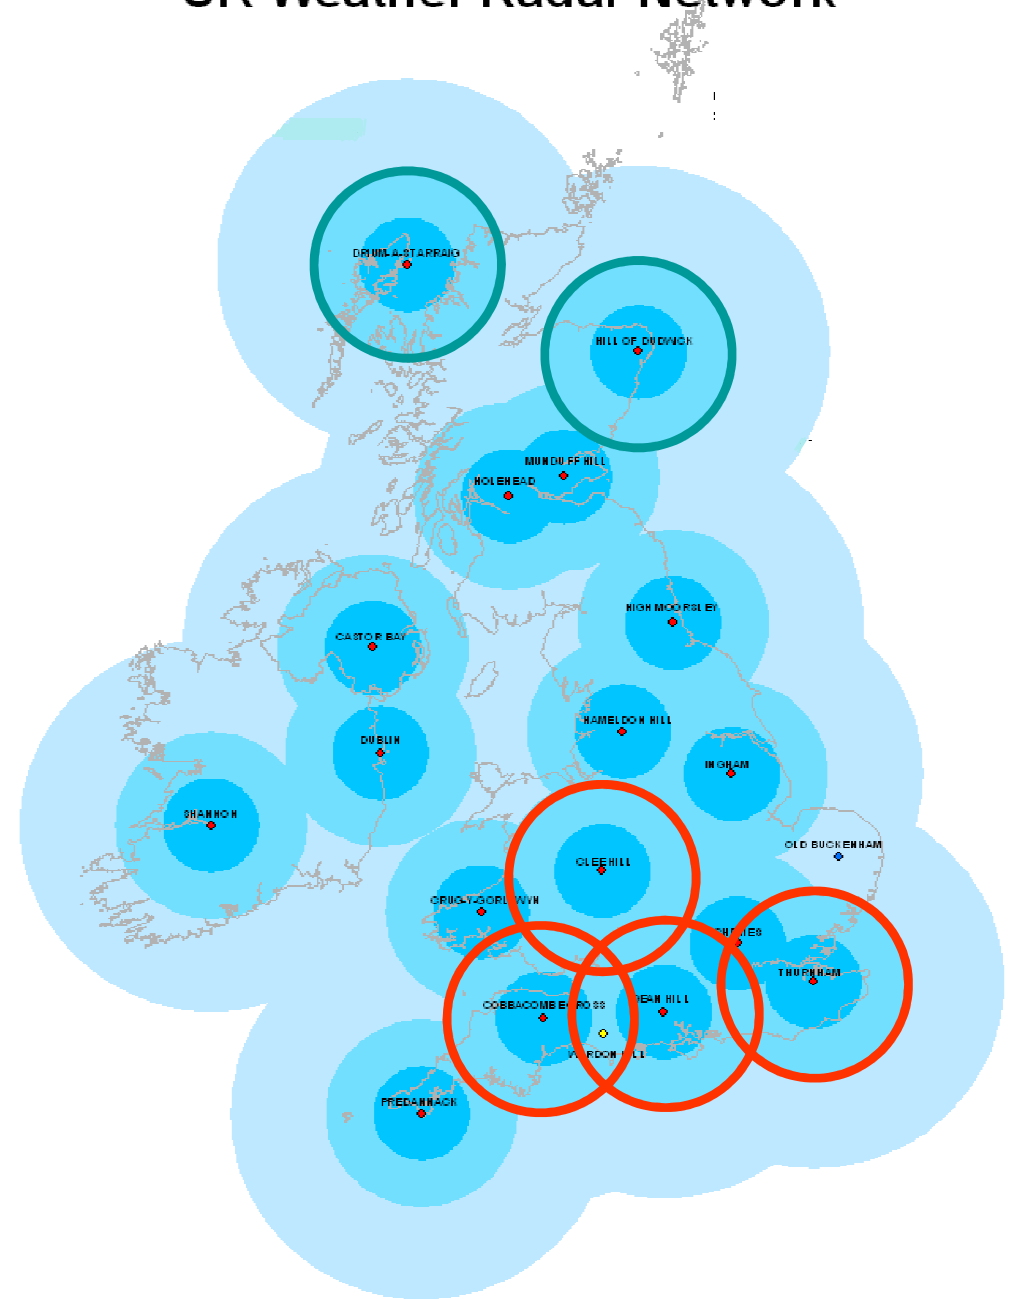

100km radius

elevations between  $1^\circ$  and  $9^\circ$

$1^\circ$  azimuthal 600m radial

every 5 minutes

## UK Weather Radar Network

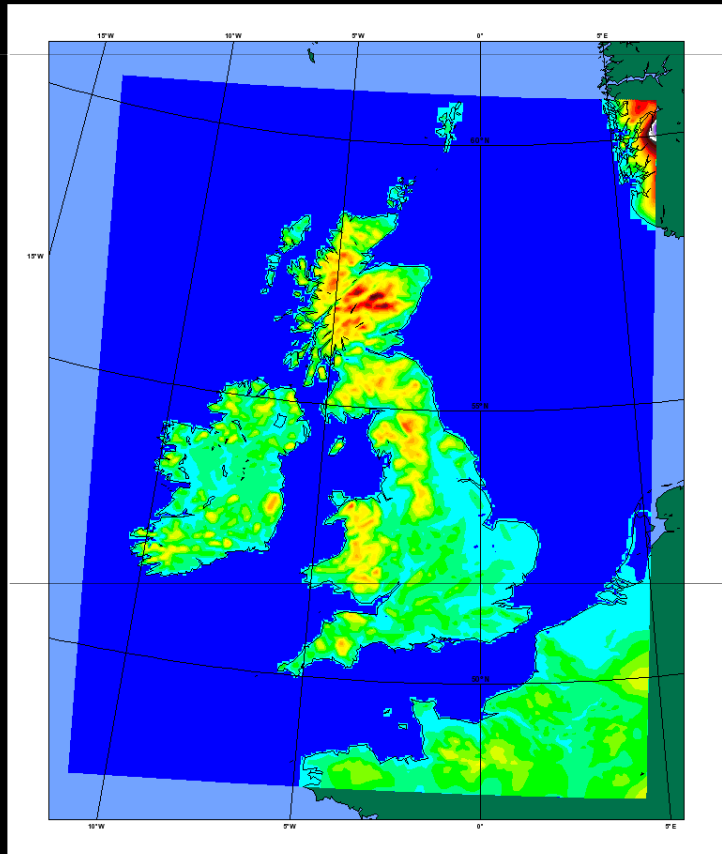

# Introduction

- During rainfall a very detailed picture of radial wind speed can be obtained.
- Local areas of convergence can be determined

# UK 4 km model set-up

3DVAR assimilation (3 hour cycles) of:

Aircraft and sonde, scatwind, satwind,  
ground GPS, SEVERI, MOPS cloud  
observations

Latent-heat nudging of:

MOPS precipitation

Adaptive vertical VAR grid

# UK 4 km control set-up

VAD winds:

Doppler radial wind information currently used to produce VAD (velocity azimuthal display) winds.

# UK 4 km trial set-up

Doppler radial winds:

Detailed radial wind information across the area of the map with Doppler radar coverage (rather than just one vertical profile per radar station).

Both require rainfall to be present

# UK 4 km Trial set-up

- Trial Period (rainy periods only)
  - 2010 August 10<sup>th</sup> 0300 – August 24<sup>th</sup> 0300 (14 days)
  - 2010 17<sup>th</sup> November 0300 – 23<sup>rd</sup> November 0300 (6 days)
  - 2010 29<sup>th</sup> November 0300 – 4<sup>th</sup> December 0300 (5 days)
  - 2010 16<sup>th</sup> December 0300 – 21<sup>st</sup> December 0300 (5 days)
  - 2010 27<sup>th</sup> December 0300 – 28<sup>th</sup> December 0300 (1 day)
  - 2011 24<sup>th</sup> January 1500 – 26<sup>th</sup> January 2100 (2 ¼ days)
  - 2011 February 9<sup>th</sup> 0300 – February 15<sup>th</sup> February 2100 (6 ¾ days)

# Trial Settings

- Observations assimilated at T+0 in a 3 hour window (T-1.5 to T+1.5).
- All periods trialled with “Poisson” thinning to 8km (twice the UM grid).
- Some trials also have simple UM grid thinning or “Poisson” thinning at 4 or 12 km.
  - Poisson thinning randomly selects observations – that must be more than the specified radius away from any other observation. (Shown to give smaller analysis error than other methods by Bondarenko et al, 11th Symposium on Integrated Observing and Assimilation Systems for the Atmosphere, Oceans, and Land Surface (IOAS-AOLS), 2007)
  - Individual groups of superrobbing cells will certainly be selected by this method whereas they might not be selected on a regular grid.

# UK Index

- Standard way to measure forecast performance before allowing new data to be assimilated
- Includes Equitable Threat Score for surface visibility, 6 hour precipitation accumulation, total cloud amount and cloud base height (with 3/8 cover).
- Includes skill for surface temperature and surface wind speed.
- Averaged over 36 hours over the whole of the UK.

## % increase in UK Index over all trials (neutral impact)

Poisson 8 km thinning (44 days)	$0.09 \pm 0.15$
Poisson 8 km thinning (14 days)	$0.05 \pm 0.27$
Poisson 12 km thinning (14 days)	$-0.29 \pm 0.27$
Poisson 4 km thinning (14 days)	$-0.23 \pm 0.27$
UM grid (4 km) thinning (14 days)	$-0.03 \pm 0.29$

Errors calculated by considering the day-to-day variation in the Index

# Doppler wind assimilation will be operational by end of June

- Number of VAR iterations required is on average the same as without the Doppler wind measurements:
  - $(97 \pm 8)\%$
- OPS times acceptable
- Can go operational
- But can we show a positive impact? Certainly by eye can see some cases where the rainfall location has improved.
- Need to look over shorter timescales and consider other verification methods

# Individual case where rainfall location is seen to be improved

mm/hr

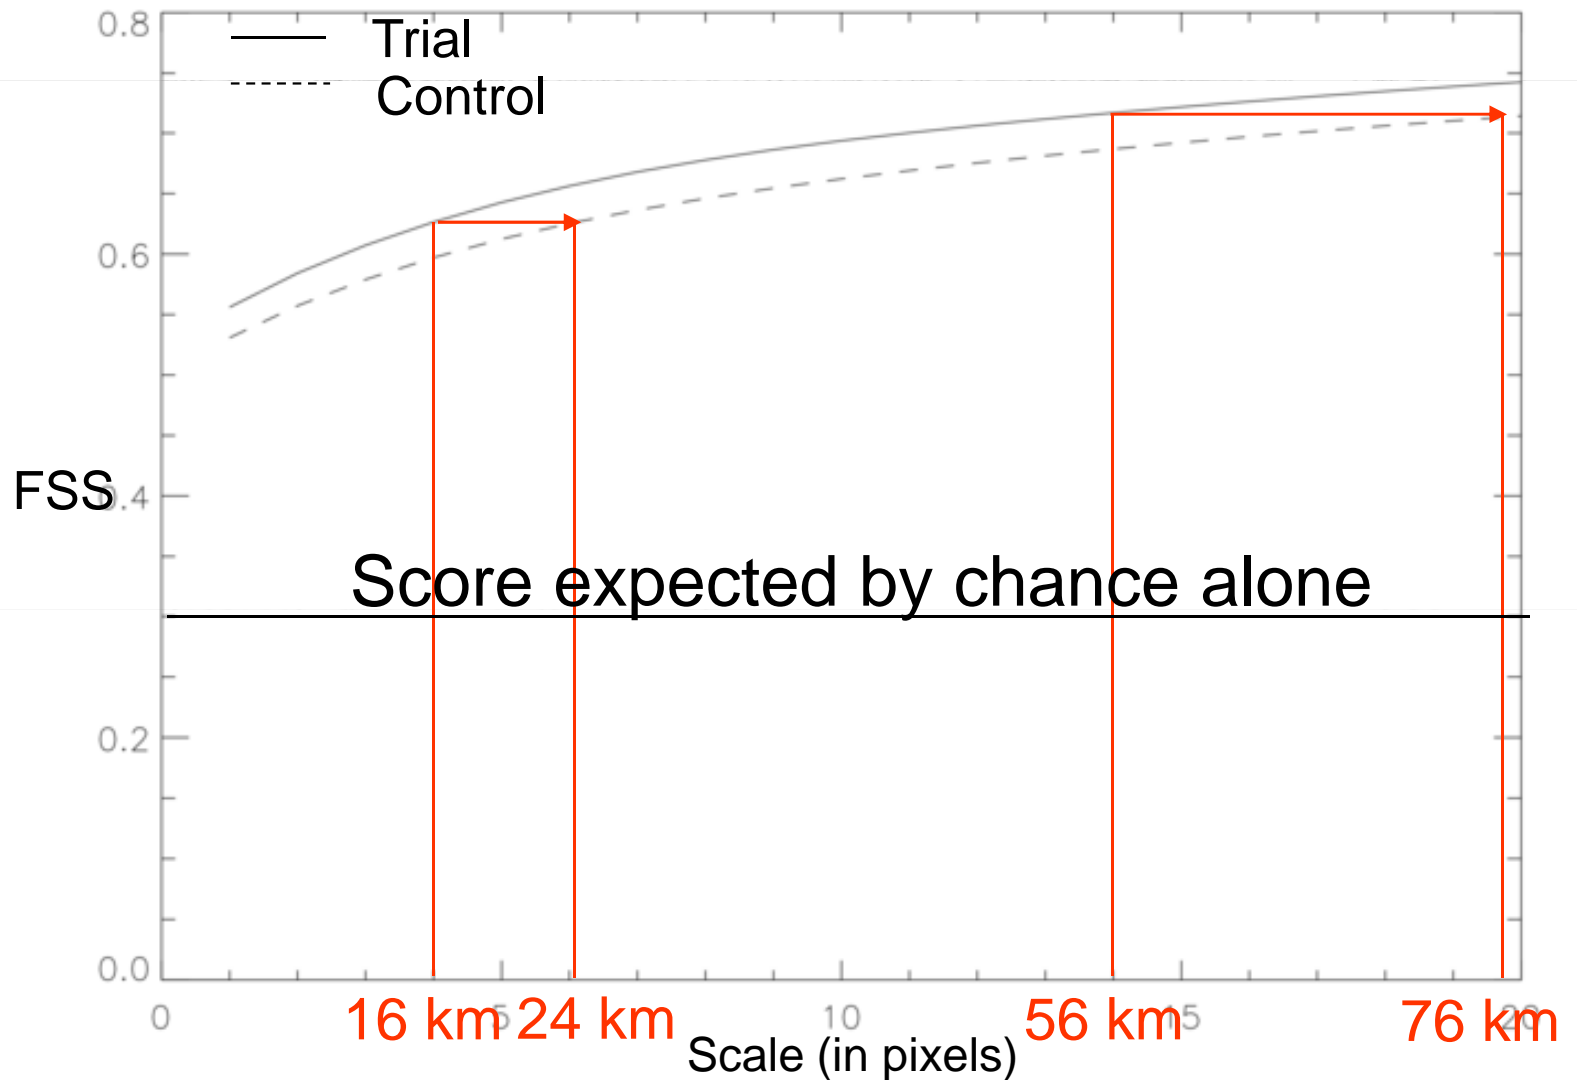

# Fraction Skill Score

- Roberts, 2008 Meteorological Applications, 15, 163 – 169
- Look at rainfall within a given box size – you can determine a scale at which the forecast is useful
- Can make allowance for the rainfall in the model being close to that in the observation but not in exactly the same pixel (the UK Index precipitation score only scores positively when the rainfall is in the same pixel).
- Compares precipitation percentiles from radar measurements and model outputs (eliminates bias)
- Considered instantaneous rates (rather than accumulations)
- Score goes from 0 to 1 – 1 being a perfect score

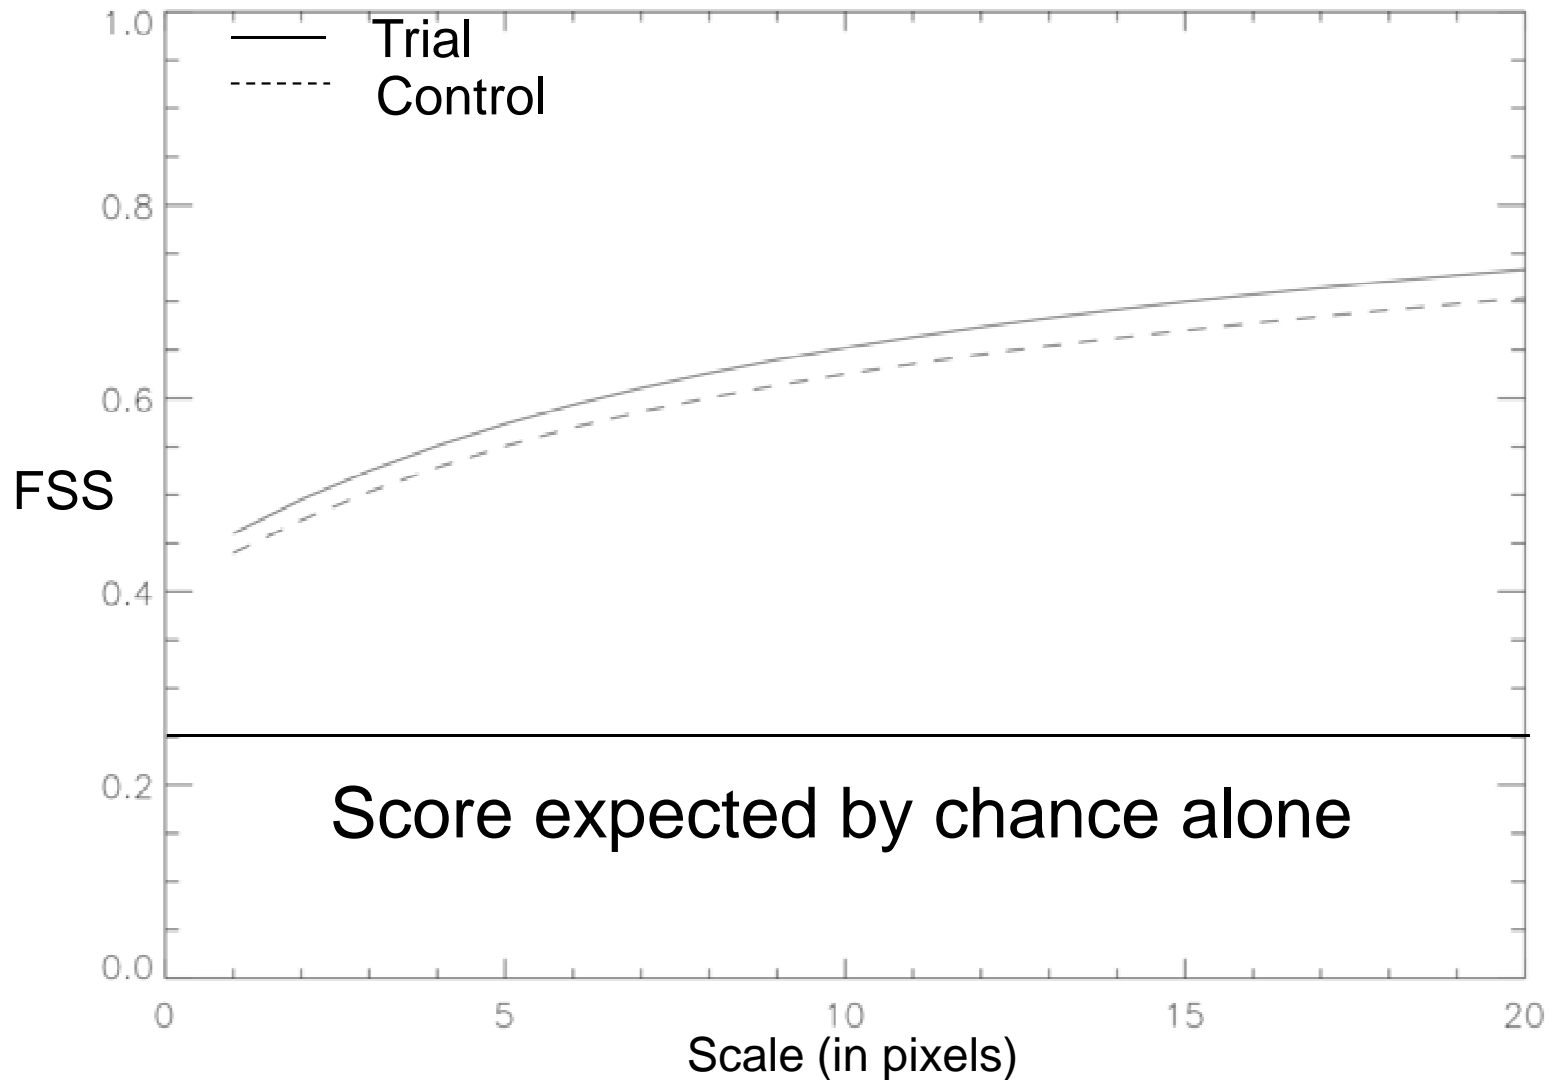

# Fraction Skill Score 75<sup>th</sup> percentile Control and Trial with Poisson thinning at 8 km plotted against scale (1<sup>st</sup> run, 1<sup>st</sup> timestep)

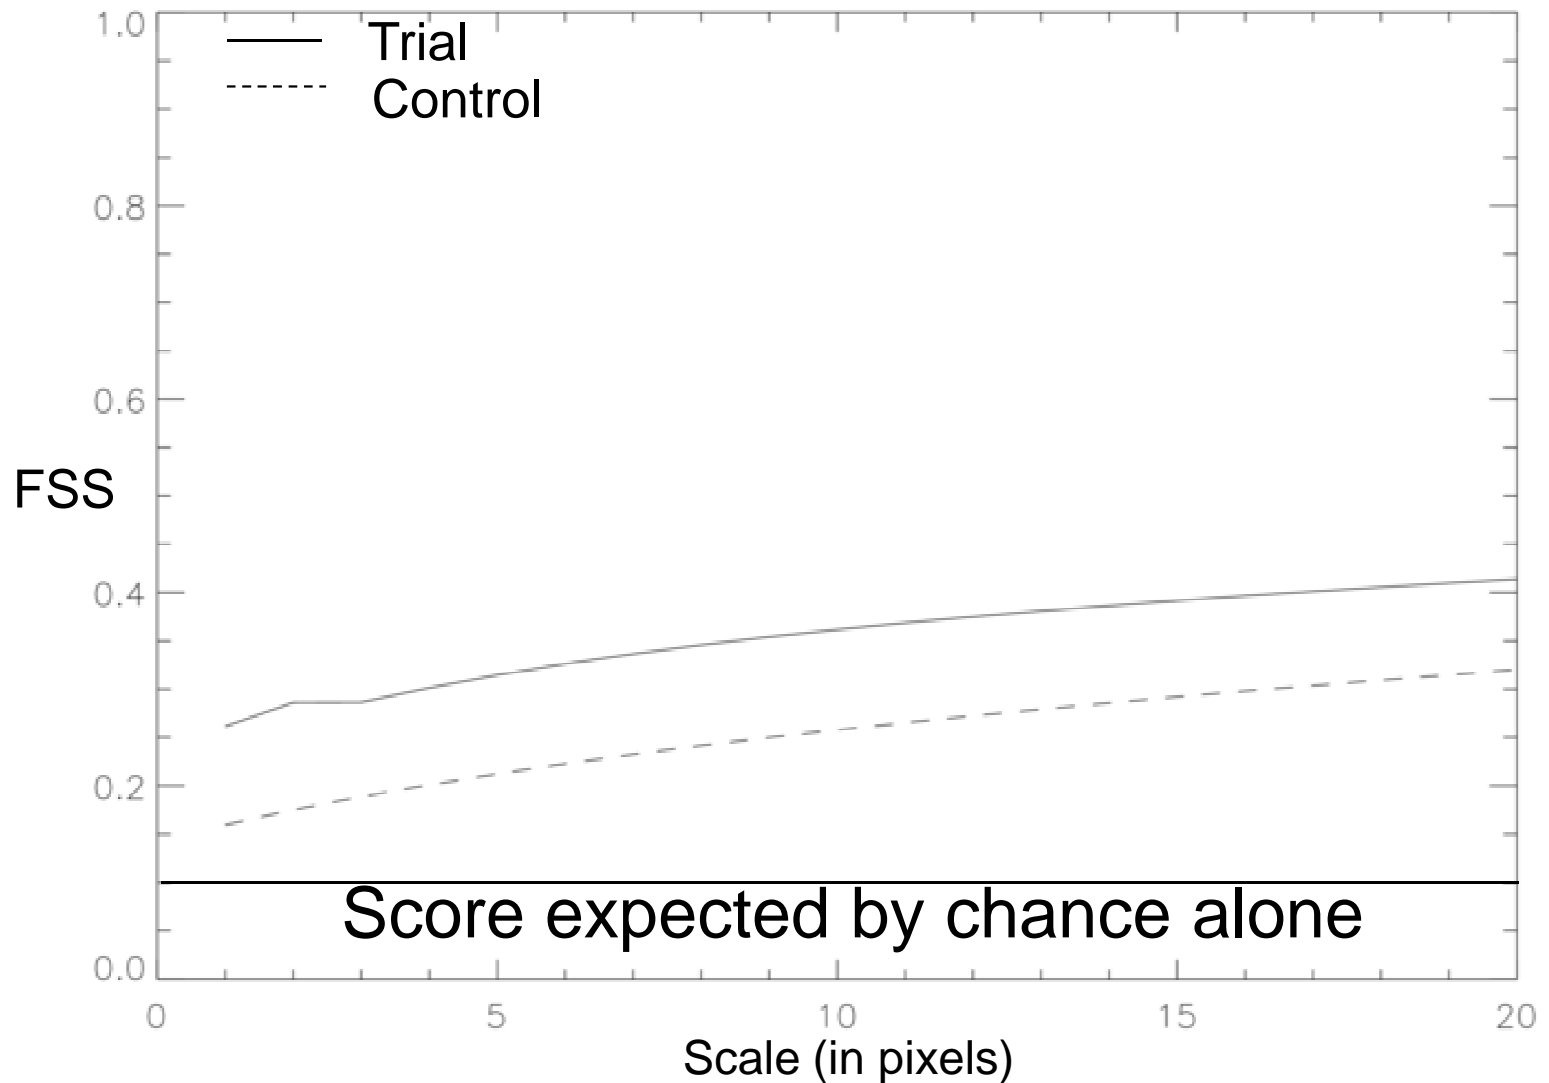

# Fraction Skill Score 75<sup>th</sup> percentile Trial with Poisson thinning at 8 km plotted against scale (average of 1st 5 runs)

# Fraction Skill Score 90<sup>th</sup> percentile Trial with Poisson thinning at 12 km plotted against scale (average of first 36 runs)

## Conclusions

- Doppler radial winds will be assimilated operationally from June.
- Overall neutral impact on the UK Index
- Improvement seen in the rainfall location

Any Questions?

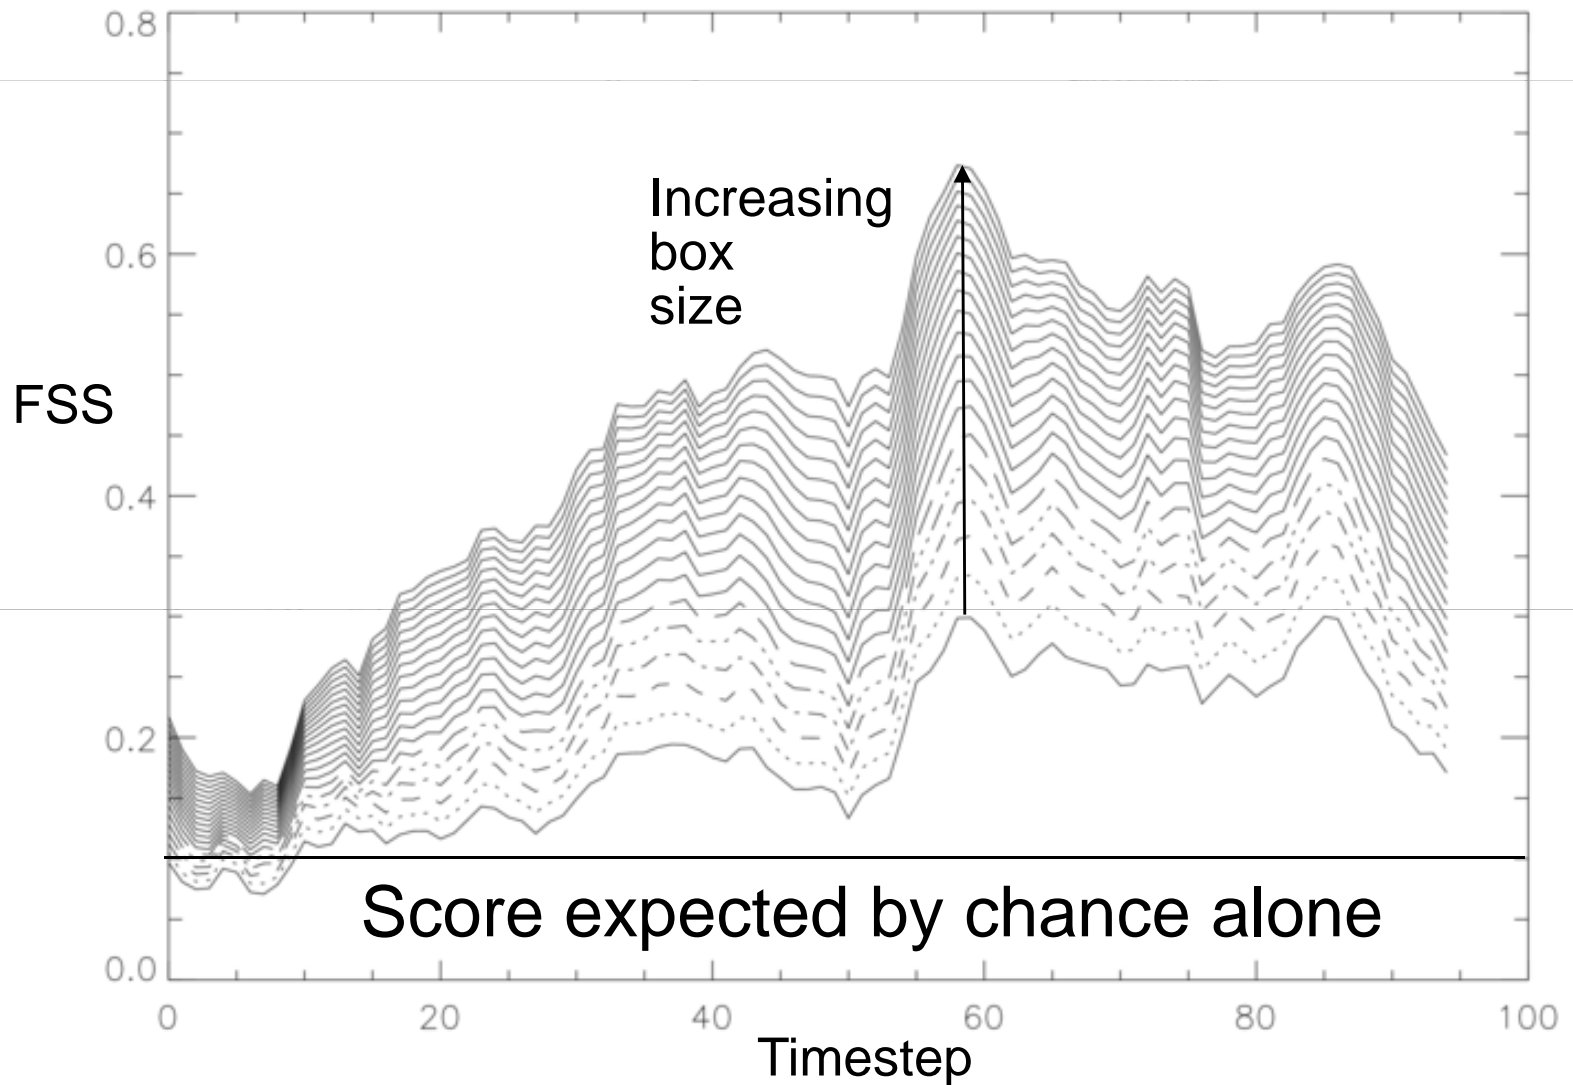

**Met Office**

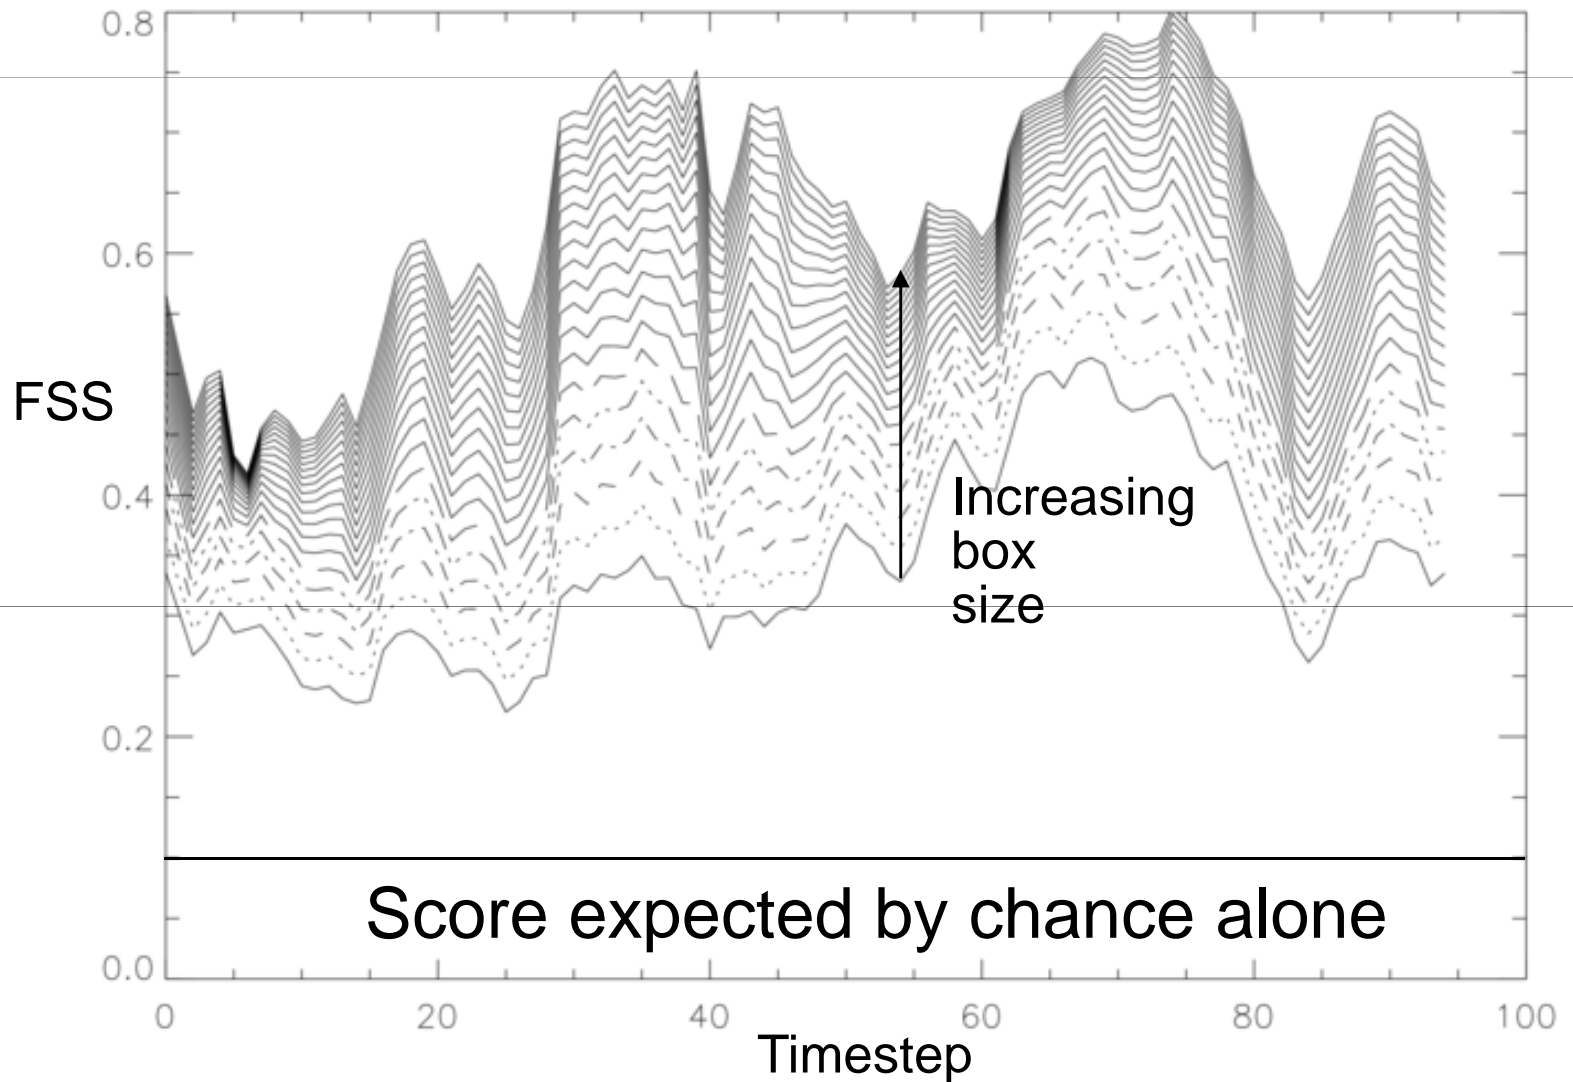

# Fraction Skill Score 90<sup>th</sup> percentile Control (without radial winds) plotted against timestep (6<sup>th</sup> run only)

# Fraction Skill Score 90<sup>th</sup> percentile Trial (with radial winds thinned to 8 km) plotted against timestep (same run)

# Quality Control

- Isolated groups of 2 or fewer pixels are rejected
- A 3x3 Laplace filter is applied – which rejects pixels that are too different from their neighbours
- Observations with a difference of greater than  $10 \text{ ms}^{-1}$  to the background are discarded
- Raw observations falling outside of 1 standard deviation of the mean of the superobbing cell are rejected
- If a superobservation cell contains only one observation it is rejected.

Met Office

# Trial Settings

- Superrobbing – Circle Near the radar, circle area limited by the arc distance. After the arc distance exceeds the value of range bin spacing, the data selection area is defined by the range bin spacing.

# Fraction Skill Score

- Roberts, 2008 Meteorological Applications, 15, 163 – 169
- Take a box of certain dimension e.g. 3x3 pixels
- Calculate how many pixels are above a threshold in forecast and observations

Model:  
Rainfall above  
Threshold in 3/9  
pixels

Observation:  
Rainfall above  
Threshold in 4/9  
pixels

Model fraction  $M_j=3/9$

Observation fraction  $O_j=4/9$

# Fraction Skill Score

- $$FBS = \frac{1}{N} \sum_{j=1}^N (O_j - M_j)^2$$
- $$FSS = 1 - (FBS / FBS_{\text{worst}})$$
- $FBS_{\text{worst}}$  when no non-zero fractions are colocated in forecast and observations
- $$FBS_{\text{worst}} = \frac{1}{N} \sum_{j=1}^N (O_j^2 + M_j^2)$$
- Varies between 0 and 1, 1 being a perfect score and 0 being the worst

# Fraction Skill Score 90<sup>th</sup> percentile Trial with Poisson thinning at 8 km plotted against timestep (same run)

# Fraction Skill Score 90<sup>th</sup> percentile Trial with Poisson thinning at 12 km plotted against timestep (same run)

# Fraction Skill Score 90<sup>th</sup> percentile Trial with grid thinning at 4 km plotted against timestep (same run)

# Fraction Skill Score 90<sup>th</sup> percentile Control plotted against timestep (24<sup>th</sup> run only)

# Fraction Skill Score 90<sup>th</sup> percentile Trial with Poisson thinning at 8 km plotted against timestep (same run)

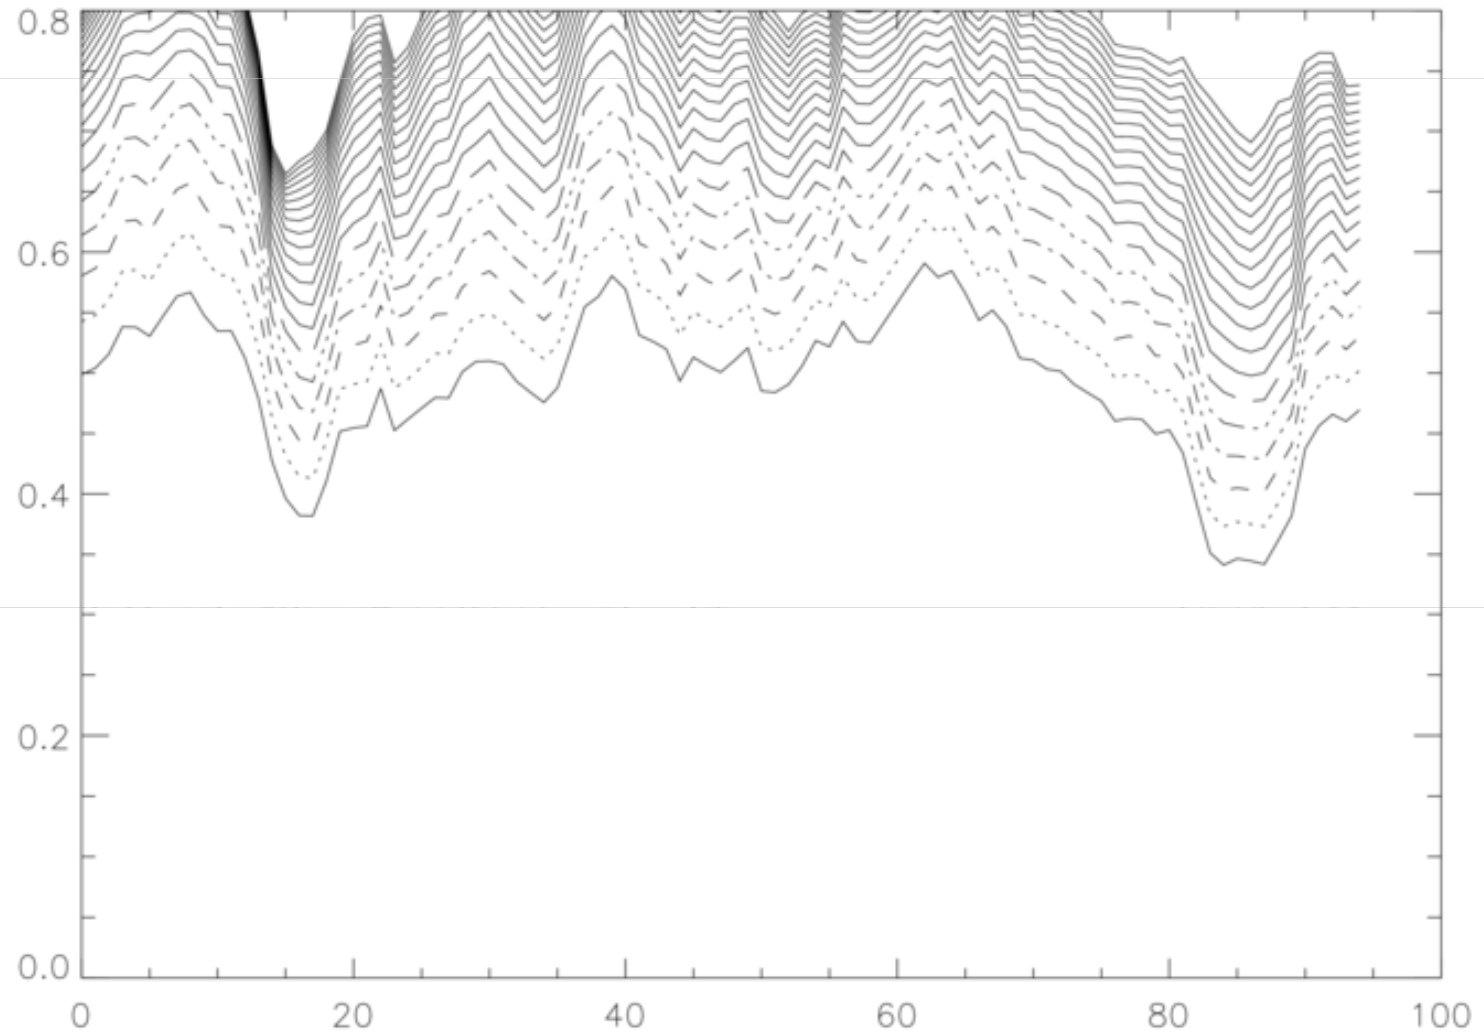

# Fraction Skill Score 90<sup>th</sup> percentile Trial with Poisson thinning at 12 km plotted against timestep (same run)

# Fraction Skill Score 90<sup>th</sup> percentile Trial with Poisson thinning at 8 km plotted against timestep (same run)

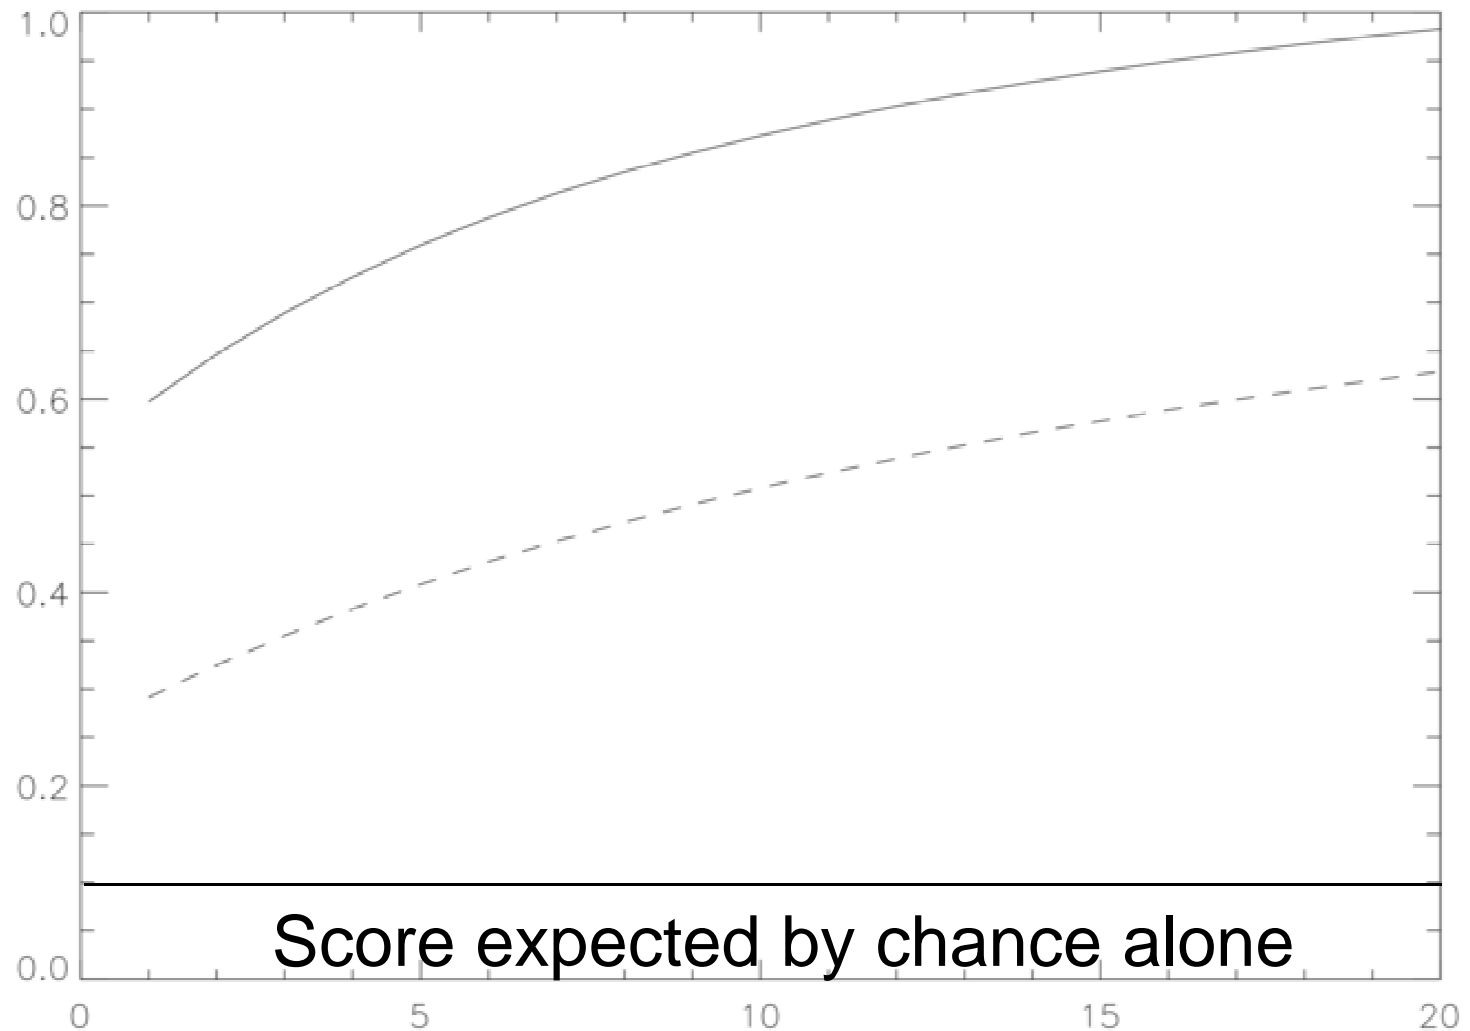

# Fraction Skill Score 90<sup>th</sup> percentile Trial with grid thinning at 4 km plotted against timestep (same run)

# Fraction Skill Score 90<sup>th</sup> percentile Trial with Poisson thinning at 12 km plotted against scale (average of 5 runs)

# Fraction Skill Score 75<sup>th</sup> percentile Control and Trial with Poisson thinning at 8 km plotted against scale (1<sup>st</sup> run, all timesteps)

Score expected by chance alone

16 km -> 17 km

56 km -> 60 km

# Cross correlation

Met Office

# Cross correlation at T+1

- Shows how likely you are to get rainfall predicted in a pixel at a given separation from an observed rainfall pixel
- Width of the function gives an idea of the useful forecast scale

Met Office

# Width of cross correlation
